# Analytical Foundations of Volterra Series * 

Stephen Boyd, L. O. Chua, and C. A. Desoer **

## 1. Introduction

A Volterra Series Operator with kernels $h_{n}$ is one of the form

$$
\begin{gather*}
N u(t)=\sum_{n=1}^{\infty} y_{n}(t)  \tag{1.1a}\\
y_{n}(t)=\int \cdots \int h_{n}\left(\tau_{1}, \tau_{2}, \ldots, r_{n}\right) u\left(t-\tau_{1}\right) u\left(t-\tau_{2}\right) \cdots u\left(t-\tau_{n}\right) d r_{1} d \tau_{2} \cdots d \tau_{n} \tag{1.1b}
\end{gather*}
$$

and is a generalization of the convolution description of linear time-invariant (LTI) operators to time-invariant (TI) nonlinear operators. These operators are important because many TI nonlinear operators occurring in engineering either have this form or can be approximated, in some sense, by operators of this form. Volterra series have been the object of much recent study. The focus has primarily been on proofs that the input/output ( $I / O$ ) operators of dynamical systems, and various generalizations, have a Volterra series representation, and the relationship between the Voiterra kernels and the geometry of the dynamical system. ${ }^{1,2}$ For example M. Fliess et al have found a simple and elegant formula for the kernels of a dynamical system in terms of various Lie derivatives. ${ }^{3}$

In contrast our focus is on the analysis involved with Volterra series. We first carefully address the basic issues of the formal Volterra series (1.1) above: what are the kernels (functions, distributions...?) and when do the integrals and sums in (1.1) make sense? In the remainder of $\mathbf{\xi}^{2}$ we examine the elementary properties of Volterra series operators, both system-theoretic (e.g. bounds on their gain and incremental gain) and mathematical (e.g. their relation to Taylor series).

In $\mathbf{\S 3}$ we use the methods of $\boldsymbol{\S} 2$ to prove some well-known formulas for the kernels of various "system interconnections". We give an elementary and complete proof of the Inversion theorem for Volterra series, and work through an illustrative example.

In $\mathbf{\delta}^{4}$ we explore some frequency domain topics. We start by proving the Steady State theorem for Volterra series operators. We then establish the validity of a general formula for the spectrum of the output in terms of the spectrum of a periodic input.

In the appendix we present more advanced (and esoteric) material: Volterra-like series, incremental gain theorem for $L^{\prime}$, Taylor series which aren't Volterra series, conditions under which the frequency domain formula of $\$ 4$ holds, and almost periodic inputs.

[^0]The results we present range from "well-known" (e.g. the Uniqueness theorem) to new (e.g. the material in the appendix). Is order to keep the paper interesting and accessible to a wide audience, we have used only the basic tools of real analysis, in a few places developing some necessary background material. We do not present the results in their full generality: we have limited the scope of the paper to single-input single-output (SISO) stable TI Volterra series in order to do a more thorough job on this important case. Extensions to other cases will be presented in a future paper.

The references we give are not meant to be complete but only representative. More complete bibliographies can be fonnd in our references, for example Sandberg [1] or Fliess et al [3].

## 2. Formulation

## ఖ.1. What are the Kernela?

In most treatments the kernels $h_{n}\left(r_{1}, \ldots, r_{k}\right)$ in equation (1.1) are interpreted as functions from $R^{\text {n }}$ to $R$. Unfortunately this interpretation rules out some operators common in engineering. We start with two examples:

## Example 1:

$$
\begin{gathered}
\dot{x}=-x+u \\
y=x^{2}
\end{gathered}
$$

and $x(0)=0$. Then

$$
\begin{gathered}
y(t)=\left\{\int_{0}^{t} e^{-r} u(t-\tau) d \tau\right\}^{2} \\
=\iint 1\left(\tau_{1}\right) 1\left(\tau_{2}\right) e^{-\left(\tau_{2}+\tau_{2}\right)} u\left(t-\tau_{1}\right) u\left(t-\tau_{2}\right) d \tau_{1} d \tau_{2}
\end{gathered}
$$

so this operator has a Volterra series description with just one nonzero kernel,

$$
h_{2}\left(\tau_{1}, \tau_{2}\right)=1\left(\tau_{1}\right) 1\left(\tau_{2}\right) e^{-\left(\tau_{1}+T_{2}\right)}
$$

This kernel $h_{2}$ is an ordinary function $: R^{2} \rightarrow R$.

## Example 28

$$
\begin{gathered}
i=-x+u^{2} \\
y=x
\end{gathered}
$$

and $x(0)=0$. Here

$$
y(t)=\int_{0}^{t} e^{-r} u(t-\tau)^{2} d \tau=
$$

$$
=\iint 1\left(\tau_{1}\right) 1\left(\tau_{2}\right) e^{-T_{2}} \delta\left(\tau_{1}-\tau_{2}\right) u\left(t-\tau_{1}\right) u\left(t-\tau_{2}\right) d \tau_{1} d \tau_{2}
$$

if you will condone the zotation. So here the kernel $h_{2}$ is not a function as it was in example 1 but a measure supported on the line $\tau_{2}=\tau_{3}$ informally given by

$$
\left.h_{2}\left(r_{1}, r_{2}\right)=1\left(r_{1}\right) 1\left(\tau_{2}\right)\right)\left(\tau_{1}-r_{2}\right) e^{-r_{1}}
$$

These examples are typical- in general the Volterra series of dynamical systems with the vector field affine in the input $u$ (e.g. in bilinear aysteme) have kernels which are ordinary functions whereas in other cases more general measures may be necessary. $2,4,5,6$ In the latter case Sandberg has called the series "Volterra-like". ${ }^{6}$ §A1 contains an in-depth discussion of Volterralike series.

A less exotic but widely occurring nonlinear operator whose description requires kernels which are measures is the memoryless operator

$$
y(t)=f(u(t))
$$

where $f: R \rightarrow R$ is analytic near 0 .
We will allow our kernels to be measures. We will see that the analysis is no harder, and the resulting theory then includes all the examples above.

### 2.2. When the Serles Converges

Recall that the ordinary power series $g(x)=\sum_{n=0}^{\infty} a_{n} x^{n}$ converges absolutely for $|x|<\rho$, where the radius of convergence is given by $\rho=\left(\lim _{n \rightarrow \infty}\left|a_{n}\right|^{1 / n}\right)^{-1}$. Similarly a radius of convergence $\rho$ can be associated with a formal Volterra series

$$
\begin{equation*}
N u(t)=y(t)=\sum_{n=1}^{\infty} \int \cdots \int h_{n}\left(\tau_{1}, \ldots, \tau_{n}\right) u\left(t-\tau_{1}\right) \ldots u\left(t-\tau_{n}\right) d \tau_{1} \ldots d \tau_{n} \tag{2.1}
\end{equation*}
$$

such that the series will converge for input signals with $|u(t)|<\rho$.
More precisely, let $B^{n}$ be the bounded measures on $R_{+}^{n}\left(R_{+} \Delta\{r \mid r \geq 0\}\right)$, with $\|\mu\|=\int d|\mu|$. For convenience we will write elements of $B^{n}$ as if they were absolutely continuous ("Physicists' style"), e.g. $h_{2}\left(\tau_{1}, \tau_{2}\right)=\delta\left(\tau_{1}-\tau_{2}\right) e^{-T_{2}}$. For signals |||| will denote the $\infty$-norm, i.e. $\|u\|=\|u\|_{\infty}$.**

Definition: By a Volterra series operator we will henceforth mean an operator given by equation (1.1) above and satisfying assumptions

[^1](A1) $h_{n} \in B^{n}$, and
(A2) $\lim _{n \rightarrow \infty}\left\|h_{n}\right\|^{1 / n}<\infty$, that is, $\left\{\left\|h_{n}\right\|^{1 / n}\right\}$ is bounded.
Our first task is to determine for which $u$ 's equation (2.1) makes sense.
Definitions If $N$ is a Volterra series operator with kernels $h_{a}$, we define the gain bound function of $N$ to be, for $x \geq 0, f(x) \Delta \sum_{n=1}^{\infty}\left\|h_{n}\right\| x^{n}$ (with extended values, that is, $f(x)$ may be $\infty$ ). The radius of convergence of $N$ is defined by $\rho=\operatorname{Rad} N \triangleq\left(\lim _{n \rightarrow \infty}\left\|h_{n}\right\|^{1 / n}\right)^{-1}$.

Assumption (A2) implies that $\rho>0$ and that the gain bound function $f$ is analytic at 0 , with normal radius of convergence $\rho$. Since all the terms in the series for $f$ are positive $\rho$ is also given by $\rho=\inf \{x \mid f(x)=\infty\}$, a formula which will be useful in $\S 3$. We can now say when (2.1) makes sense:

## Theorem 2.2.1 (Gain Bound Theorem):

Suppose $N$ is a Volterra series operator with kernels $h_{n}$, gain bound function $f$, and radius of convergence $\rho$. Then
(I) the integrals and sum in equation (2.1) above converge absolutely for inputs with $\|u\|<p$, that is, in $B_{\rho p}$ the ball of radius $\rho$ in $L^{\infty}$.
(II) $N$ satisfies $\|N u\| \leq f(\|u\|)$ and consequently $N$ maps $B_{,}$into $L^{\infty}$.
(II) is partial justification for naming $f$ the gain bound function, we'll soon see more. Theorem 2.2.1 is well known (in various forms). $8,0,2,10,11,5,12,1$

Proots

$$
\int \cdots \int \mid h_{n}\left(r_{2}, \ldots, r_{n}\right) u\left(t-\tau_{1}\right) \ldots u\left(t-\tau_{n}\right)\left\|d \tau_{1} \ldots d \tau_{n} \leq\right\| h_{n}\| \| u \|^{n}
$$

In pasticular, the integrals make sense. If $\|u\|<\rho$, then

$$
\begin{gathered}
\sum_{n=1}^{\infty}\left|\int \cdots \int h_{n}\left(\tau_{1}, \ldots, r_{n}\right) u\left(t-r_{1}\right) \ldots u\left(t-r_{n}\right) d \tau_{1} \ldots d r_{n}\right| \\
\leq \sum_{n=1}^{\infty} \int \cdots \int\left|h_{n}\left(r_{1}, \ldots, \tau_{n}\right) u\left(t-r_{1}\right) \ldots u\left(t-r_{n}\right)\right| d \tau_{1} \ldots d \tau_{n} \\
\leq \sum_{n=1}^{\infty}\left\|h_{n}\right\|\|u\|^{n}=f(\|u\|)<\infty
\end{gathered}
$$

which establishes absolute convergence of the series and the gain bound in (II). O
For convenience we adopt the notational convention that throughout this paper $N$ will denote a Volterra series operator with kernels $h_{n}$, gain bound function $f$, and radius of convergence $\rho$.

The Gain Bound theorem has many simple applications. For example, the tail of the gain bound function gives a bound on the truncation error for a Volterra series.

## Corollary 2.2.2 (Error Bound for Truncated Voltarra Serien):

The truncated Volterra series operator defined by

$$
N^{(t)}(t) \triangleq \sum_{n=1}^{t} \int \cdots \int h_{n}\left(r_{1}, \ldots, \tau_{n}\right) u\left(t-r_{1}\right) \ldots u\left(t-\tau_{n}\right) d \tau_{1} \ldots d \tau_{n}
$$

satisfies

$$
\left\|N u-N^{(k)_{u}}\right\| \leq \sum_{n=\infty}^{\infty}\left\|h_{n}\right\|\|u\|^{n}
$$

which is $o\left(\|u\|^{k}\right)$.

### 2.3. Dlementary Propertiess Continulty

We will now show that $N$ is continuous on $B_{p}$ and Lipschitz continuous on any $B_{r}, r<\rho$.
Lemma 2.3.1: Suppose $\|u\|+\|v\|<\rho$. Then

$$
\|N(u+v)-N(u)\| \leq f(\|u\|+\|v\|)-f(\|u\|) \leq f^{\prime}(\|u\|+\|v\|)\|v\|
$$

Proof: Assume $\|u\|+\|v\|<\rho$. Then $\|u+v\|<\rho$ so $N(u+v)$ makes sense and

$$
\begin{gather*}
|N(u+v)(t)-N(u)(t)| \leq  \tag{2.2a}\\
\leq \sum_{n=1}^{\infty} \int \cdots \int\left|h_{n}\left(r_{1}, \ldots, r_{n}\right)\left\{\prod_{i=1}^{n}(u+v)\left(t-r_{i}\right)-\prod_{i=1}^{n} u\left(t-r_{i}\right)\right\}\right| d r_{1} \ldots d r_{n}  \tag{2.2b}\\
\leq \sum_{n=1}^{\infty}\left\|h_{n}\right\| \sum_{j=1}^{n-1}\left(\frac{n}{j}\right)\|u\|^{j}\|v\|^{n-j}  \tag{2.2c}\\
==\sum_{n=1}^{\infty}\left\|h_{n}\right\| \|\left\{(\|u\|+\|v\|)^{n}-\|u\|^{n}\right\}  \tag{2.2d}\\
=f\left(\|u\|^{n}+\|v\|\right)-f(\|u\|) \tag{2.2e}
\end{gather*}
$$

This technique will recur so careful explanation is worthwhile. In (2.2b) the first product, when expanded, has $2^{n}$ terms; the second product is precisely the first term in the expansion. Replacing the remaining $2^{n}-1$ terms by their norms and integrating yields (2.2c).

The final inequality in lemma 2.3 .1 follows from the mean value theorem, since

$$
f(\|u\|+\|v\|)-f(\|u\|)=f^{\prime}(s)\|v\|
$$

where $\|u\| \leq s \leq\|u\|+\|v\|$ and $f^{\prime}$ is increasing. Thus $f^{\prime}$ can be interpreted as an incremental gain bound function for $N$.

Theorem 2.3.2 (Incremental Gain Theorem)s Let $B_{r}$ be the ball of radius $r$ in $L^{\infty}$, and suppose $r<\rho$. Then
(I) $N: B_{r} \rightarrow B_{f(r)}$ is Lipschitz continuous,
(II) $N: B \rightarrow L^{\infty}$ is continuous.

Prooft Suppose $u$ and $v$ are in $B_{r}$. From the Gain Bound Theorem

$$
\begin{equation*}
\|N u-N v\| \leq f(\|u\|)+f(\|v\|) \tag{2.3}
\end{equation*}
$$

We claim that

$$
\begin{equation*}
\|N u-N v\| \leq f(\|u-v\|+\|v\|)-f(\|v\|) \tag{2.4}
\end{equation*}
$$

For $\|u-v\|+\|v\|<\rho(2.4)$ is simply lemma 2.3.1; for $\|u-v\|+\|v\| \geq \rho(2.4)$ is true since its righthand side is $\infty$. From (2.3) and (2.4) we deduce

$$
\begin{aligned}
& \|N u-N v\| \leq \min \{f(\|u-v\|+\|v\|)-f(\|v\|), f(\|u\|)+f(\|v\|)\} \\
& \leq\|u-v\| \min \left\{\frac{f(r+\|u-v\|)-f(r)}{\|u-v\|}, \frac{2 f(r)}{\|u-v\|}\right\} \leq K\|u-v\|
\end{aligned}
$$

where $K$ is the $\max$ of the expression $\min \{\cdots\}$ for $0 \leq\|u-v\| \leq 2 r$. $K$ is in fact $2 f(r) /\left(f^{-1}(3 f(r))-r\right)$ and is quite finite (see figure 1 ). This establishes $(1)$; since ( 1 ) is true for any $r<\rho$ (II) follows. 0

We will soon see that $N$ is much more than merely continuous; for example, $N$ has Frechet derivatives of all orders on $B_{\rho}$. But before moving on, we present an extension of the last theorem which will be important in $\boldsymbol{\$ 4}$.

Recall that for linear systems $y=h_{1} * u$ we have the result $\|y\|_{p} \leq\left\|h_{1}\right\|\|u\|_{p}$, for $1 \leq p \leq \infty$. ${ }^{15}$ It turns out that when properly reformulated the Gain Bound theorem and the Incremental Gain theorem are also true with general $p$-norms. First some warnings for $p<\infty$ : a Volterra series operator need not be defined on any open subset of $L^{p}$ (e.g. $N u(t)=u(t) /(1-u(t)))$, and even when it is, it need not map $L^{p}$ back into $L^{p}$ (e.g. $\left.\mathrm{Nu}(t)=u(t)^{2}\right)$. For more details and discussion we refer the reader to §A2.

Theorem 2.3.3 (Gain Bound theorem for $L^{p}$ ): For $1 \leq p \leq \infty$

$$
\|N u\|_{D} \leq\|u\|_{P} \frac{f(\|u\|)}{\|u\|}
$$

(unmarked norms are $\infty$-norms).
Even though our next theorem is stronger, we give the proof here to demonstrate the basic argument.

Proof:

$$
\begin{align*}
& \left|y_{n}(t)\right| \leq \int \cdots \int\left|A_{n}\left(r_{2} \ldots, r_{n}\right) u\left(t-\tau_{1}\right) \ldots u\left(t-r_{n}\right)\right| d \tau_{1} \ldots d \tau_{n} \\
& \leq\|u\|^{n-1} \int\left\{\int \cdots \int\left|A_{n}\left(\tau_{2} \ldots, r_{n}\right)\right| d \tau_{2} \ldots d \tau_{n}\right\}\left|u\left(t-\tau_{1}\right)\right| d \tau_{1} \tag{2.5}
\end{align*}
$$

Now the bracketed expression in (2.5) is a mecoure in $r_{1}$ with norm $\left\|h_{n}\right\|$, hence using the result for linear systems cited above we have ${ }^{18}$

$$
\left\|y_{n}\right\|_{p} \leq\|u\|^{n-1}\left\|h_{n}\right\|\|u\|_{p}
$$

Thus

$$
\|N u\|_{p} \leq \sum_{n=1}^{\infty}\left\|y_{n}\right\|_{p} \leq\|u\|_{p} \sum_{n=1}^{\infty}\left\|h_{n} \mid\right\| u\left\|^{n-1}=\right\| u \|_{p} \frac{f(\|u\|)}{\|u\|}
$$

which establishes theorem 2.3.3.O
Lemma 2.3.4s

$$
\|(N(u+v)-N u)\|_{p} \leq\|v\|_{p} \frac{f(\|u\|+\|v\|)-f(\|u\|)}{\|v\|} \leq\|v\|_{p} f^{\prime}(\|u\|+\|v\|)
$$

The proof combines the proof above with the proof of the Incremental Gain theorem and is in §A2.

Theorem 2.3.5 (Incremental Gain theorem for $L^{p}$ ): Let $B_{r}$ be the ball of radius $r$ in $L^{\infty}$, with $r<\rho$. Then there is a $K$ such that

$$
\|N u-N v\|_{\Phi} \leq K\|u-v\|_{p}
$$

The proof is identical to that of theorem 2.3.2 and so is omitted.

### 2.4. Multilinear and Polynomial Mappings

This section contains mostly background material for $\$ 2.5$ and may be skipped by those familiar with the topic. There are many good references on this material, both in mathematics ${ }^{14,15}$ and engineering. ${ }^{16,17}$

Note that the $n$th term $y_{n}$ in a Volterra series is homogeneous of degree $n$ in the input $u$. Indeed much more is true; it is a polynomial mapping in $u$.
Definitions Let $V$ and $W$ be vector spaces over $R$. Then $M: V^{a} \rightarrow W$ is said to be multilinear or $n$-linear if it is linear in each argument separately, i.e. if

$$
M\left(v_{1}, \ldots v_{j}+\alpha w, \ldots v_{n}\right)=M\left(v_{1}, \ldots v_{j}, \ldots v_{n}\right)+\alpha M\left(v_{1}, \ldots w, \ldots v_{n}\right)
$$

Example 1: $V=R^{n}, M\left(v_{1}, v_{2}\right)=v_{1}^{T} A v_{2} A \in M_{n \times n}$

Example 2: Let $V=W=L^{\infty}, h \in B^{2}$ and

$$
M\left(u_{1}, u_{2}\right)=\iint h\left(r_{1}, r_{2}\right) u_{1}\left(t-r_{1}\right) u_{2}\left(t-r_{2}\right) d \tau_{1} d \tau_{2}
$$

Definitions Let $M: V^{n} \rightarrow W$ be $n$-linear. Then a map $P: V \rightarrow W$ of the form

$$
P(v)=M(v, \ldots v)
$$

is said to be an $n$-order polynomial mapping.
Example 3: Let $V=W=L^{\infty}, h \in B^{2}$ and

$$
P(u)=\iint h\left(\tau_{1}, \tau_{2}\right) u\left(t-\tau_{1}\right) u\left(t-\tau_{2}\right) d \tau_{1} d \tau_{2}
$$

And in general the $n$th term of a Volterra series operator is an $n$-order polynomial mapping in the input $u$.

Theorem 2.4.1: An $n$-order polynomial mapping is homogeneous of degree $n$, but the converse is not true.

Prooft $P(\alpha v)=M(\alpha v, \ldots \alpha v)=\alpha^{n} M(v, \ldots v)=\alpha^{n} P(v)$.
To see that the converse is not in general true, let $V=R^{2}, W=R$, and consider

$$
F\left(x_{1}, x_{2}\right)=\left(\left|x_{1}\right|+\left|x_{2}\right|\right)^{2}=x_{1}^{2}+x_{2}^{2}+2\left|x_{1} x_{2}\right|
$$

$F$ is homogeneous of degree two but is not a polynomial mapping, since a second order polynomial mapping satisfies $P\left(x_{1}+x_{2}\right)+P\left(x_{1}-x_{2}\right)=2 P\left(x_{1}\right)+2 P\left(x_{2}\right) ; F$ does not.

This distinction between a homogeneous mapping and a polynomial mapping is like the difference between a general norm and a norm which comes from an inner product. To bring the discussion home to engineering consider the nonlinear TI operator $\tilde{\mathcal{N}}$ given by

$$
\bar{N} u(t)=F(u(t), u(t-1))
$$

$\bar{N}$ is homogeneous of degree two. We will see later that the response of a second order Volterra series operator to an input of the form $u(t)=\cos \omega t$ has, at most, two components: one at D.C. and one at $2 \omega$. $\bar{N}(\cos \omega t)$, however, has infinitely many harmonics. O

We need just a few more definitions:
Defintions An $n$-linear map $M$ is said to be symmetric if for any permutation $\sigma \in S^{\pi}$

$$
M\left(v_{\sigma 1}, \ldots, v_{\sigma_{n}}\right)=M\left(v_{1}, \ldots, v_{n}\right)
$$

Thus the bilinear map of example 1 is symmetric iff $A=A^{T}$, and the bilinear map of example 2 is symmetric iff $h\left(\tau_{1}, \tau_{2}\right)=h\left(\tau_{2}, \tau_{1}\right)$.

Definitions SYMM is the multilinear mapping defined by

$$
\operatorname{SYMM}\left(v_{1}, \ldots, v_{n}\right) \triangleq \frac{1}{n!} \sum_{\sigma \in S^{*}} M\left(v_{\sigma 1}, \ldots, v_{\sigma n}\right)
$$

and similarly if $h_{n}$ is a function or measure, we define

$$
\mathbf{S Y M} h_{n}\left(\tau_{1}, \ldots, r_{n}\right) \triangleq \frac{1}{n!} \sum_{\theta \in S^{*}} h_{\pi}\left(\tau_{\sigma 1}, \ldots, r_{\sigma n}\right)
$$

SYMM derives its importance from:
Theorem 2.4.2: Suppose the polynomial maps $P_{1}$ and $P_{2}$ are induced by multilinear maps $M_{1}$ and $M_{2}$, respectively. Then $P_{1}=P_{2}$ if $S Y M M_{1}=S Y M M_{2}$.

Thus two bilinear maps of the form of example 1 induce the same polynomial map if and only if $A_{1}+A_{1}^{T}=A_{2}+A_{2}^{T}$.

Proof: First note that SYMM and $M$ always induce the same polynomial map, since

$$
\operatorname{SYM} M(v, \ldots, v)=\frac{1}{n!} \sum_{v \in S^{*}} M(v, \ldots, v)=M(v, \ldots, v)
$$

The "if" part follows. In the next section we will prove more than the "only if" part, so here we will give just an informal sketch of how the "only if" proof goes. The key is the formula

$$
\begin{equation*}
\left.\frac{1}{n!} \frac{\partial^{n}}{\partial \alpha_{1} \ldots \partial \alpha_{n}}\right|_{0=0} P\left(\sum_{i=1}^{n} \alpha_{i} v_{i}\right)=\operatorname{SYM} M\left(v_{1}, \ldots, v_{n}\right) \tag{2.6}
\end{equation*}
$$

so that $P_{1}=P_{2}$ implies $\mathbf{S Y M M}_{1}=\mathbf{S Y M M}_{2}$. To "establish" the formula, note that

$$
P\left(\sum_{i=4}^{n} \alpha_{i} v_{i}\right)=\sum_{i_{l}=1}^{n} \cdots \sum_{i_{n}=4}^{\pi} \alpha_{i_{1}} \ldots \alpha_{i_{2}} M\left(v_{i_{1}}, \ldots, v_{i_{n}}\right)
$$

The only terms which contribute to

$$
\left.\frac{1}{n!} \frac{\partial^{n}}{\partial \alpha_{1} \ldots \partial \alpha_{n}}\right|_{0=0}
$$

are the $n!$ terms where the $\left(i_{j}\right)$ are a permutation of $(1,2, \ldots, n)$, and the resulting sum is SYMM ( $\left.v_{1}, \ldots, v_{n}\right)$. Of course we don't know yet that these derivatives exist, but we will see later that if the multilinear operators are bounded, then these derivatives can be interpreted as honest Frechet derivatives.

This process of determining SYMM from the polynomial map $P$ induced by $M$ is known as polarization. In fact, we could replace the formula (2.6) above involving partial derivatives with a purely algebraic one; for example for $n=2$ we have the polarization formula

$$
\operatorname{SYMM}\left(u_{1}, u_{2}\right)=P\left(\frac{u_{1}+u_{2}}{2}\right)-P\left(\frac{u_{1}-u_{2}}{2}\right)
$$

We gave the formula (2.6) because it generalizes to whole Volterra Series; the algebraic identities do not.

Let us now assume that $V$ and $W$ are Banach spaces. Then an $n$-linear map $M: V^{n} \rightarrow W$ is bounded if

$$
\begin{equation*}
\sup _{\left\|0_{i}\right\| \leq 2}\left\|M\left(v_{1}, \ldots, v_{n}\right)\right\|<\infty \tag{2.7}
\end{equation*}
$$

in which case we call the lefthand side of (2.7) the norm of $M$ as a maltilinear operator and denote it $\|M\|_{M a}$. The bilinear operator of example 1 is bounded, with $\|M\|_{M}=\sigma(A) . *$ The bilinear operator in example 2 is bounded with norm at most $\left\|h_{2}\right\| * *$.

We now quickly review derivatives in Banach space. ${ }^{15,14}$ Recall that $L(V, W)$ denotes the Banach space of bounded linear maps from $V$ into $W$, with the operator norm $\|A\| \Delta \sup \{\|A v\|\|\|v\| \leq 1\}$. A map $N: G \rightarrow W$, where $G$ is an open subset of $V$, is said to have a Frechet or strong derivative $D N\left(u_{0}\right) \in L(V, W)$ at $u_{0} \in G$ if

$$
\left\|N\left(u_{0}+u\right)-N\left(u_{0}\right)-D N\left(u_{0}\right) u\right\|=o(\|u\|)
$$

If the map $u_{0} \rightarrow D N\left(u_{0}\right)$ has a Frechet derivative, we say $N$ has a second Frechet derivative $D^{(2)} N\left(u_{0}\right)$ and it is an element of $L(V, L(V, W))$. Fortunately this space can be identified with $L_{2}(V, W)$, the space of bounded bilinear maps : $V^{2} \rightarrow W$, with the norm $\left\|\|_{M a}\right.$ defined above. Similarly the $n$th Frechet derivative, if it exists, can be thought of as a bounded $n$-linear map $: V^{n} \rightarrow W$. It can be shown that $D^{(n)} N\left(u_{0}\right)$ is symmetric, e.g. if $D^{(n+1)} N\left(u_{0}\right)$ exists.

We now have all the background material necessary for

### 2.5. Relation to Taylor Series; Uniquenes of Volterra Series

We will now see that Volterra series operators are Taylor series. As pointed out by M. Fliess et als this is not true of unstable Volterra series operators (those not satisfying assumption (A1)) which are more properly viewed as perturbational expansions.

## Theorem 2.5.1 (Frechet Derivatives of Volterra Saries Operatorn):

On $B, N$ bas Frechet derivatives of all orders with

$$
\begin{gather*}
D^{(k)} N\left(u_{0}\right)\left(u_{1}, \ldots, u_{k}\right)(t)=  \tag{2.8a}\\
=8 Y M \sum_{n=k}^{\infty} n(n-1) \ldots(n-k+1) \int \ldots \int h_{n}\left(\tau_{1}, \ldots, r_{n}\right) \prod_{i=1}^{k} u_{i}\left(t-\tau_{i}\right) d \tau_{i} \prod_{i=k+1}^{n} u_{0}\left(t-\tau_{i}\right) d \tau_{i} \tag{2.8b}
\end{gather*}
$$

Thus $\left\|D^{(t)} N\left(u_{0}\right)\right\| \leq f^{(t)}\left(\left\|u_{0}\right\|\right)$ and $(n!)^{-1} D^{(n)} N(0)$ is the $n$-linear mapping associated with the $n$th term of the Volterra series and given by:

$$
\frac{1}{n!} D^{(n)} N(0)\left(u_{1}, \ldots, u_{n}\right)(t)=\int \ldots \int h_{n}\left(\tau_{1}, \ldots, \tau_{n}\right) u_{1}\left(t-\tau_{1}\right) \ldots u_{n}\left(t-\tau_{n}\right) d \tau_{1} \ldots d \tau_{n}
$$

- (A) means the largest singular value of $A$; here we assume the Eaclidean norm on $R^{\text {B }}$.
- The actual norm, rather than this upper boand, is hard to compate; see jAs.

Remark: Theorem 2.5.1 tells us that the Volterra series we have considered so far are in fact Taylor series of operators : $L^{\infty} \rightarrow L^{\infty}$. The reader may wonder whether the Volterra series constitute all of the Taylor series of TI nonlinear maps : $L^{\infty} \rightarrow L^{\infty}$. In §A3 we show that this is not true, but that the Taylor series left out are not important in engineering.

Proof: Let $M_{k}$ denote the multilinear map given in (8b) above. We will show that

$$
N\left(u_{0}+u\right)-\sum_{k=0}^{n} \frac{1}{k!} M_{k}(u, \ldots, u)=o\left(\|u\|^{n+1}\right)
$$

which will prove $M_{k}=D^{(k)} N\left(u_{0}\right)$ as claimed. First note that

$$
\left\|M_{k}\right\| \leq \sum_{n=2}^{\infty} n(n-1) \ldots(n-k+1)\left\|h_{n} \mid\right\| u_{0} \|^{n-k}=f^{(k)}\left(\left\|u_{0}\right\|\right)
$$

Now

$$
N\left(u_{0}+u\right)=\sum_{n=4}^{\infty} \int \cdots \int \mathbf{S Y M} h_{n}\left(\tau_{1}, \ldots, \tau_{n}\right) \sum_{k=0}^{n}\left(\begin{array}{l}
n  \tag{2.9}\\
k
\end{array} \prod_{i=a}^{k} u_{i}\left(t-\tau_{i}\right) d \tau_{i} \prod_{i=k+1}^{n} u_{0}\left(t-\tau_{i}\right) d \tau_{i}\right.
$$

For $\|u\|$ small enough $\left(\|u\|+\left\|u_{0}\right\|<\rho\right.$ will do) the entire righthand side of equation (2.9) is absolutely convergent so we may rewrite it as:

$$
\begin{gathered}
=\sum_{k=0}^{\infty} \frac{1}{k!} \sum_{n=k}^{n \geq k} n(n-1) \ldots(n-k+1) \int \cdots \int g Y M h_{n}\left(\tau_{1}, \ldots, \tau_{n}\right) \prod_{i=1}^{k} u_{i}\left(t-\tau_{i}\right) d \tau_{i} \prod_{i=k+1}^{n} u_{0}\left(t-\tau_{i}\right) d \tau_{i} \\
\cdots \sum_{k=0}^{\infty} \frac{1}{k!} M_{k}(u, \ldots, u)
\end{gathered}
$$

Thus we have

$$
\begin{gathered}
\left\|N\left(u_{0}+u\right)-\sum_{k=0}^{n} \frac{1}{k!} M_{k}(u, \ldots, u)\right\| \leq \sum_{k=+1}^{\infty} \frac{1}{k!}\left\|M_{k}\right\|\|u\|^{k} \\
\leq \sum_{k=1}^{\infty} \frac{1}{k!} f^{(k)}\left(\left\|u_{0}\right\|\right)\|u\|^{k}=f\left(\left\|u_{0}\right\|+\|u\|\right)-\sum_{k=0}^{n} \frac{1}{k!} f^{(k)}\left(\left\|u_{0}\right\|\right)\|u\|^{k}
\end{gathered}
$$

which is indeed $o\left(\|u\|^{x+1}\right) \cdot 0$

## Theorem 2.5 .2 (Uniquenems Theorem for Volterra series): Suppose $N$ and $M$ are Volterra

 series operators with kernels $h_{n}$ and $g_{n}$, respectively.Then $N=M$ iff $S Y M h_{n}=S Y M g_{n}$ for all $n$.
Note that $N=M$ asserts equality of maps from some ball in $L^{\infty}$ into $L^{\infty}$, whereas the conclusion asserts equality of a sequence of measures.
Proors The "ir" part is clear, (see theorem 2.4.2). To show the "only if" part we will show that the measures $\mathbf{S Y M} h_{n}$ are determined by the operator $N$. A measure $\mu \in \mathrm{B}^{n}$ is determined by its integral over all $n$-rectangles in $\boldsymbol{R}^{\boldsymbol{n}}$, i. e. by the integrals

$$
\begin{equation*}
\int \cdots \int \mu\left(\tau_{1}, \ldots, \tau_{n}\right) u\left(-r_{1}\right) \ldots u\left(-\tau_{n}\right) d \tau_{1} \ldots d \tau_{n} \tag{2.10}
\end{equation*}
$$

where each $u_{i}$ is the characteristic function of an interval. Now by theorem 2.5 .1 we have

$$
\begin{gathered}
\int \cdots \int S Y M h_{n}\left(r_{1}, \ldots, r_{n}\right) u_{1}\left(-r_{2}\right) \ldots u_{n}\left(-r_{n}\right) d r_{1} \ldots d r_{n} \\
=\frac{1}{n!} D^{(n)} N\left(u_{1}, \ldots, u_{n}\right)(0)
\end{gathered}
$$

so that $N$ determines the integrals in (2.10) and hence the measure $\mathbf{S Y M} h_{n}$. A more explicit formula for these integrals is:

$$
\begin{gathered}
\int \cdots \int S Y M h_{n}\left(r_{1}, \ldots, r_{n}\right) u_{1}\left(-r_{1}\right) \ldots u_{n}\left(-\tau_{n}\right) d r_{1} \ldots d \tau_{n} \\
\quad=\left.\frac{1}{n!} \frac{\partial^{n}}{\partial \alpha_{1} \ldots \partial \alpha_{n}}\right|_{a=0} N\left(\sum_{i=1}^{n} \alpha_{i} u_{i}\right)(0)
\end{gathered}
$$

which is the formula mentioned in the previous section. 0
The Uniqueness theorem tells us that we may as well choose our kernels $h_{\mathrm{n}}$ to be symmetric, and from now on we will assume that all kernels are symmetric. Of course other canonical forms are possible and in some cases more convenient. For example the triangular kernels satisfy

$$
h_{\text {trin }}\left(\tau_{1}, \ldots, \tau_{n}\right)=0 \quad \text { unless } \quad 0 \leq \tau_{1} \leq \ldots \leq \tau_{n}
$$

and the Volterra series is then

$$
N u(t)=\sum_{n=1}^{\infty} \int_{0}^{t} \int_{0}^{T_{1}} \cdots \int_{0}^{T_{2}} h_{t r i}\left(r_{1}, \ldots, r_{n}\right) u\left(t-r_{1}\right) \ldots u\left(t-r_{n}\right) d r_{1} \ldots d r_{n}
$$

These kernels are often convenient in the study of dynamical systems.
One point worth mentioning: the triangle inequality implies

$$
\left\|S X M h_{n}\right\|=\left\|h_{\text {tri } i n}\right\| \leq\left\|h_{n}\right\|
$$

Thus using the symmetric (or triangular) kernels can only decrease the gain bound function $f$ and hence increase the radius of convergence $\rho$. In the sequel we will refer to the gain bound function and radius of convergence computed from the symmetric kernels as the gain bound function and radius of convergence of $\boldsymbol{N}$.

### 2.6. Final Comments on the Formulation

The formulation we have given is by no means the only possible. For example, we could interpret the norms on input signals and kernels as $L^{2}$ norms, leaving the norm on output signals (i.e. $y=N u$ ) an $L^{\infty}$ norm. Input signals and kernels would thus be $L^{2}$ functions with $\left\|h_{n}\right\| \triangleq\left\|h_{n}\right\|_{2}=\left(\int \ldots \int h_{n}\left(\tau_{1}, \ldots, \tau_{n}\right)^{2} d \tau_{1} \ldots d \tau_{n}\right)^{1 / 2}$. Then with the exception of the $L^{p}$ material of §2.3 all the preceding results hold. This is essentially the Fock space framework proposed by
deFigueiredo et al.*18

## 3. Applications to System Theory

In this section we apply the ideas of the previous section to give simple rigorous proofs of some well-known theorems. We show that the sum, pointwise product, and composition of two Volterra series operators have Volterra series and we bound their gain functions. We proceed to find the condition under which a Volterra series operator has an inverse and compute its kernels. This is applied to show that the I/O operator of a simple dynamical system is given by a Volterra series.

This program of working out the Volterra series of various "system interconnections" was first carried out at MIT in the late $1950^{\prime}{ }^{\prime},{ }^{9,10}$ but none of this work is rigorous. This constructive approach is not really a fully modern approach, where one powerful general theorem would prove all these theorems (and more). ${ }^{1}$ Unfortunately this one powerful theorem may be so general and abstract that the underlying simplicity of the formulas may be lost. In this section we want to demonstrate two things: First, that supplying the analytical details in the MT work is relatively straightforward; and second, that the resulting formulas, though complicated, are just simple extensions of the same formulas for ordinary power series. This of course should be expected in view of theorem 2.5.1.

The notation for this section is as follows: $A$ and $B$ will denote Volterra series operators with kernels $a_{n}$ and $b_{n}$, gain bound functions $f_{A}$ and $f_{B}$, and radii of convergence $\rho_{A}$ and $\rho_{B}$, respectively.

### 3.1. Sum and Product Operator

The pointwise product of $A$ and $B$ is defined by

$$
[A \cdot B] u(t)=[A u](t)[B u](t)
$$

Definitions if $a \in B^{n}, b \in B^{k}$ then the symmetric tensor product $a \vee b \in B^{n+k}$ is defined by:

$$
a \vee b\left(\tau_{1}, \ldots, \tau_{n+k}\right) \triangleq \mathbf{S Y M a}\left(r_{1}, \ldots, \tau_{n}\right) b\left(r_{n+1}, \ldots, \tau_{n+k}\right)
$$

By the product we mean the normal product measure. (Thus $h(\tau) g(\tau)$ doesn't necessarily make sense, but $h\left(\tau_{1}\right) g\left(\tau_{2}\right)$ does.) Note that

$$
\begin{gathered}
\|a \vee b\|=\int \ldots \int\left|S Y M a\left(\tau_{1}, \ldots \tau_{n}\right) b\left(\tau_{n+1}, \ldots \tau_{n+k}\right)\right| d \tau_{1} \ldots d \tau_{n+k} \\
\leq \frac{1}{(n+k)!} \sum_{\sigma \in S^{n+k}} \int \ldots \int\left|a\left(\tau_{\sigma 1}, \ldots, \tau_{\sigma n}\right) \| b\left(\tau_{\sigma n+1}, \ldots, \tau_{\sigma n+k}\right)\right| d \tau_{1} \ldots d \tau_{n+k}
\end{gathered}
$$

- Oar Volterra series with radii exceeding $r$ would be almost all of the Fock space with weights $n!r^{n}$.

$$
=\|a\|\|b\|
$$

Theorem 3.1.1 (Product Operator)z $\boldsymbol{A} \cdot \boldsymbol{B}$ is a Volterra series operator with kernels

$$
h_{n}=\sum_{k=1}^{s-1} a_{k} V b_{n-k}
$$

and characteristic gain function $f_{A \cdot B} \leq f_{A} f_{B}$. In particular, $p_{A: B} \geq \min \left\{\rho_{A}, \rho_{B}\right\}$.
Remark: If we write a Volterra series as a formal sum

$$
a_{1}+\cdots+a_{n}+\cdots
$$

then we can write the formal symmetric tensor product of $a_{1}+\cdots$ and $b_{1}+\cdots$ as

$$
\left(a_{1}+\cdots\right) V\left(b_{1}+\cdots\right)=\left(a_{1} V b_{3}\right)+\left(a_{1} V b_{2}+a_{2} V b_{1}\right)+\cdots
$$

so the Volterra series of $\boldsymbol{A} \cdot \boldsymbol{B}$ is the formal symmetric tensor product of the Volterra series of $\boldsymbol{A}$ and $B$. Note the similarity with the formula for the coefficients of the product of two power series.

Proofs Let $\|u\|<\min \left\{\rho_{A}, \rho_{B}\right\}$. Then $A u$ and $B u$ make sense and

$$
\begin{gather*}
A \cdot B u(t)=\left\{\sum_{m=1}^{\infty} \int \ldots \int a_{m}\left(\tau_{1}, \ldots, \tau_{m}\right) \prod_{i=1}^{m} u\left(t-r_{i}\right) d \tau_{i}\right\}\left\{\sum_{n=1}^{\infty} \int \ldots \int b_{n}\left(\tau_{1} \ldots, \tau_{n}\right) \prod_{i=1}^{n} u\left(t-\tau_{i}\right) d \tau_{i}\right\}  \tag{3.1a}\\
=\sum_{m=-1}^{\infty} \sum_{n=1}^{\infty} \int \ldots \int a_{m}\left(\tau_{1}, \ldots \tau_{m}\right) b_{n}\left(\tau_{m+1}, \ldots \tau_{m+n}\right)_{i=1}^{m+n} u\left(t-\tau_{i}\right) d \tau_{i}  \tag{3.1b}\\
=\sum_{n=1}^{\infty} \int \ldots \int\left\{\sum_{t=1}^{n-1} a_{k} \vee b_{n-k}\right\} u\left(t-\tau_{1}\right) \ldots u\left(t-\tau_{n}\right) d \tau_{1} \ldots d \tau_{n} \tag{3.1c}
\end{gather*}
$$

All of the changes in the order of summation and integration in equation (3.1) are justified by the Fubini theorem, since

$$
\begin{aligned}
& \sum_{m=1}^{\infty} \sum_{n=m}^{\infty} f \ldots \int \mid a_{m}\left(\tau_{1} \ldots \tau_{m}\right) b_{n}\left(\tau_{m+1}, \ldots \tau_{m+n}\right) \prod_{i=1}^{m n} u\left(t-\tau_{i}\right) \|^{m} \tau_{i} \\
& \leq \sum_{m==1}^{\infty} \sum_{n=1}^{\infty}\left\|a_{n}\right\|\left\|b_{m}\right\|\|u\|^{m+x}=f_{A}(\|u\|) f_{B}(\|u\|)<\infty
\end{aligned}
$$

Since equation (3.1) holds for any $u$ with $\|u\|<\min \left\{\rho_{A}, \rho_{B}\right\}$, the Uniqueness theorem tells us that $\sum_{k=1}^{s-1} a_{k} V b_{n-k}$ are the kernels of $A \cdot B$. Now

$$
\begin{aligned}
f_{A \cdot B}(x)= & \sum_{n=1}^{\infty}\left\|h_{n}\right\| x^{n}=\sum_{n=1}^{\infty} \sum_{k=1}^{n-1}\left\|a_{k} V b_{n-k}\right\| x^{n} \\
& \leq \sum_{n=m}^{\infty} \sum_{k=1}^{\infty}\left\|a_{k}\right\|\left\|b_{n-k}\right\| x^{n-k}
\end{aligned}
$$

$$
=\left\{\sum_{n=-4}^{\infty}\left\|a_{n}\right\| x^{n}\right\}\left\{\sum_{n=n}^{\infty}\left\|b_{n}\right\| x^{n}\right\}=f_{A}(x) f_{B}(x)
$$

The final conclusion $\rho_{A \cdot B} \geq \min \left\{\rho_{A}, \rho_{B}\right\}$ follows from $f_{A \cdot B} \leq f_{A} f_{B}$ and $\rho_{A \cdot B}=\inf \left\{x \mid f_{A \cdot B}=\infty\right\}$. 0

Theorem 3.1.2 (Sum Operstor): $A+B$ is a Volterra series operator with kernels

$$
h_{n}\left(\tau_{1}, \ldots, \tau_{n}\right)=a_{n}\left(\tau_{1}, \ldots, \tau_{n}\right)+b_{n}\left(\tau_{1}, \ldots, \tau_{n}\right)
$$

and gain bound function $f_{A+B} \leq f_{A}+f_{B}$. Thus $\rho_{A+B} \geq \min \left\{\rho_{A}, \rho_{B}\right\}$.
The proof is left to the reader.

### 3.2. Composition Operator

The composition of $A$ and $B$, which we denote by the juxtaposition $A B$, is defined by

$$
|A B| u(t) \underset{\sim}{\Delta} A(B u)(t)
$$

To motivate the formula for the kernels of $A B$, recall that the $n$th coefficient of the composition of the ordinary power series $\sum_{l=1} a_{l} x^{l}$ and $\sum_{l=1} b_{l} x^{l}$ is given by

$$
\sum_{k=1}^{n}\left\{\begin{array}{c}
\substack{i_{2}, i_{i} \geq 1 \\
i_{1}+\cdots+i_{z}=\cdots} \tag{3.2}
\end{array}\right\} a_{k} b_{i_{2}} \cdots b_{i_{k}}
$$

Theorem 3.2.1 (Composition Theorem): $A B$ is a Volterra series operator with kernels

$$
\begin{align*}
& h_{n}\left(t_{1}, \ldots, t_{n}\right)=S Y M \sum_{k=1}^{n}\left\{\sum_{\substack{i_{1}, \ldots, i_{k} \geq 1 \\
i_{2}+\ldots+t_{k} \geq n}}\right\} \int \ldots \int a_{k}\left(\tau_{2} \ldots, \tau_{k}\right) \cdot  \tag{3.3a}\\
& \cdot b_{i_{2}}\left(t_{1}-\tau_{1}, \ldots t_{i_{2}}-r_{1}\right) \cdots b_{i_{k}}\left(t_{n-i_{k}+1}-\tau_{k}, \ldots t_{n}-\tau_{k}\right) d \tau_{1} \ldots d \tau_{k} \tag{3.3b}
\end{align*}
$$

Moreover $f_{A B}(x) \leq f_{A}\left(f_{B}(x)\right)$. Thus $\rho_{A B} \geq \min \left\{\rho_{B}, f_{B}^{-1}\left(\rho_{A}\right)\right\}$.
Proofs Let $h_{n}$ be defined by the formula (3.3) above. First note that

$$
\begin{equation*}
\left\|h_{\pi}\right\| \leq \sum_{k=\{ }^{\pi}\left\{\sum_{\substack{i_{1}, \ldots, i_{2} \geq 1 \\ i_{1}+\cdots+i_{2}=-\cdots}}\right\}\left\|a_{t}\right\|\left\|b_{i_{2}}\right\| \cdots\left\|b_{i_{k}}\right\| \tag{3.4}
\end{equation*}
$$

and the righthand side of (3.4) is the $n$th coefficient of $f_{A}\left(f_{B}(\cdot)\right)$, so $f_{H}(x) \leq f_{A}\left(f_{B}(x)\right)$. This compatation justifies the changes of order of integration and summation in the following.

Suppose $f_{A}\left(f_{B}(\|u\|)\right)<\infty$. Then $B u$ makes sense and $\|B u\| \leq f_{B}(\|u\|)$ so $A B u$ makes sense and:

$$
\begin{aligned}
& A B u(t)=\sum_{k=1}^{\infty} \int \cdots \int a_{k}\left(r_{1} \ldots, r_{k}\right) B u\left(t-\tau_{1}\right) \cdots B u\left(t-\tau_{k}\right) d \tau_{1} \ldots d \tau_{k} \\
& =\sum_{k=1}^{\infty} \int \ldots \int a_{k}\left(\tau_{1}, \ldots, \tau_{k}\right) \prod_{i=1}^{k}\left\{\sum_{m=1}^{\infty} \int \ldots \int b_{m}\left(t_{1}, \ldots t_{m}\right) u\left(t-r_{i}-t_{1}\right) \ldots u\left(t-\tau_{i}-t_{m}\right) d t_{1} \ldots d t_{m}\right\} d \tau_{i}
\end{aligned}
$$

$$
\begin{aligned}
& \cdot u\left(t-\tau_{1}-t_{1}\right) \ldots u\left(t-\tau_{1}-t_{i_{2}}\right) \ldots u\left(t-\tau_{k}-t_{i_{2}}+\ldots+i_{k-1}+1\right) \ldots u\left(t-\tau_{k}-t_{i_{1}}+\ldots+i_{2}\right) d t_{1} \ldots d t_{i_{1}}+\ldots+i_{2} d \tau_{1} \ldots d \tau_{k}
\end{aligned}
$$

We now collect terms by degree in $u$ to get:

$$
\begin{aligned}
& =\sum_{n=1}^{\infty} \int \cdots \int\left\{\sum _ { t = 1 } ^ { n } \left\{\sum_{\substack{i_{2}, \ldots, i_{2} \geq 1 \\
i_{2}+\ldots+i_{k} \geq=n}} a_{k}\left(r_{1} \ldots, r_{k}\right) \cdot\right.\right.
\end{aligned}
$$

Finally, we change the $t_{i}$ variables:

$$
\begin{aligned}
& =\sum_{n=m}^{\infty} \int \cdots \int\left(\sum_{k=1}^{n}\left\{\sum_{\substack{i_{1}, \ldots, i_{k} \geq 1 \\
i_{1}+\ldots+i_{k}=\cdots n}}\right) \int \ldots \int a_{k}\left(\tau_{1}, \ldots, \tau_{k}\right) \cdot\right. \\
& \left.\cdot \delta_{i_{2}}\left(t_{1}-r_{1}, \ldots, t_{i_{2}}-r_{1}\right) \cdots \delta_{i_{1}}\left(t_{n-i_{1}+1}-r_{k}, \ldots, t_{n}-r_{k}\right) d \tau_{1} \ldots d r_{k}\right\} u\left(t-r_{1}\right) \ldots u\left(t-r_{n}\right) d t_{1} \ldots d t_{n} \\
& =\sum_{n=1}^{\infty} h_{n}\left(\tau_{1}, \ldots, \tau_{n}\right) u\left(t-\tau_{1}\right) \ldots u\left(t-\tau_{n}\right) d \tau_{1} \ldots d \tau_{n}
\end{aligned}
$$

and the uniqueness theorem tells us $h_{\mathrm{s}}$ are the kernels of $A B$. Equation (3.4) establishes the bouad $f_{A B} \leq f_{A} f_{B}$, and the lower bound on the radius of convergence of $A B$ follows. $O$

### 3.3. Inverses of Volterra Serles Operators

We now ask the question: when does a Volterra series operator have a local inverse near 0 given by a Volterra series operator and what are its kernels? Whole papers have been written on this important topic. ${ }^{16,20}$ Just like ordinary power series, the condition is just that the first term be invertible.

## Theorem 3.3.1 (Inveraion Theorem for Volterra Serfes):

$A$ has a local inverse at $\mathbf{0}$ if and only if its first kernel $a_{1}$ is invertible in $\mathbf{B}^{\mathbf{1}}$, i.e. there exists a measure $b_{1} \in B^{1}$ with $a_{1} \neq b_{1}=\delta$.
-Siace the convolation of measares in $\mathbf{B}^{\mathbf{1}}$ is commatative, $a_{1}{ }^{\circ} b_{2}=\delta$ implies $b_{1}{ }^{\circ} a_{1}=\delta$.

Remark: Since the Frechet derivative of $A$ at 0 is given by convolution with $a_{1}$ (theorem 2.5.1), the Inversion theorem can be thought of as a generalized Inverse function theorem. We will not pursue this idea further: instead we take a constructive approach.

Proof: To see the "only if" part, suppose $A$ has a local inverse $B$, that is

$$
\begin{equation*}
A B=B A=I \tag{3.5}
\end{equation*}
$$

where $I$ is the identity operator ( $I_{1}=\delta_{1} I_{n}=0$ for $n>0$ ). Using the composition theorem to compute the first kernel of the operators in equation (3.5) yields

$$
a_{1} * b_{1}=b_{1} * a_{3}=\delta
$$

Thus $a_{1}$ is invertible in $B^{1}$.
The proof of the "ir" part will proceed as follows: we first construct a right inverse for $A$ under the assumption that the first kernel is just $\delta$. Using this we show that $A$ has a right inverse in the general case, $a_{1}$ invertible in $B^{\mathbf{l}}$. We finish the proof by showing that the right inverse constructed is in fact also a left inverse for $\boldsymbol{A}$.

Special Case: Assume for now that $a_{1}=\delta$. To motivate what follows, consider an ordinary power series $a(x) \Delta \sum_{n=1}^{\infty} a_{n} x^{n}$ with $a_{1}=1$. Since $a^{\prime}(0)=1, a(\cdot)$ has an analytic inverse $b(x) \Delta \sum_{n=1}^{\infty} b_{n} x^{n}$ near 0 . Using formula (3.3) for the coefficients of the composition $a(b(x))=x$ yields $b_{1}=1$ and the following recursive formula for $b_{n}$ :

$$
\begin{equation*}
b_{n}=-\sum_{k=2}^{n}\left\{\sum_{\substack{i_{1}, \ldots, i_{k} \geq 1 \\ i_{2}+\ldots+i_{k}=m}}\right\} a_{k} b_{i_{2}} \cdots b_{i_{k}} \tag{3.7}
\end{equation*}
$$

Note that since the index $k$ starts at two, the righthand side of (3.7) refers only to $b_{1}, \ldots, b_{n-1}$. Incidently this process of recursively computing the coefficients of the inverse of an analytic function is known as reversion of a power series. ${ }^{21}$

We now use the same construction for Volterra series. Let $b_{1}=\delta$ and for $n>1$ define measures $b_{n} \in B^{n}$ recursively by

$$
\begin{align*}
& \delta_{n}\left(r_{1}, \ldots, r_{n}\right)=- \text { SYM } \sum_{k=2}^{n}\left\{\sum_{\substack{i_{1}, \ldots, i_{k} \geq 1 \\
i_{2}+\ldots+i_{k}}}\right\} \int \ldots \int a_{k}\left(r_{1}, \ldots, r_{k}\right) \cdot  \tag{3.8a}\\
& \cdot b_{i_{1}}\left(t_{1}-\tau_{1}, \ldots t_{i_{1}}-r_{1}\right) \cdots b_{i_{k}}\left(t_{n-i_{k}+1}-\tau_{k}, \ldots t_{n}-\tau_{k}\right) d \tau_{1} \ldots d \tau_{k} \tag{3.8b}
\end{align*}
$$

As in (3.7) above this comes directly from the composition formula and $(A B)_{n}=0, n>1$. We now have to show that $b_{n}$, as defined in (3.8) above, are actually the kernels of a Volterra series
operator: we must verify that assumptions (A1) and (A2) hold.
We establish (Al) by induction. First note that $b_{1}=\delta \in B^{1}$. Assuming that $b_{j} \in B^{j}$ for $j=1, \ldots, n-1$ (3.8) implies that $b_{n} \in B^{n}$, with

$$
\begin{equation*}
\left\|b_{n}\right\| \leq \sum_{k=2}^{\pi}\left\{\sum _ { \substack { i _ { 1 } , i _ { k } \geq 1 \\ i _ { 2 } + \cdots + i _ { k } = n } } \left|\left\|a _ { k } \left|\left\|\mid b_{i_{2}}\right\| \cdots\left\|b_{i_{k}}\right\|\right.\right.\right.\right. \tag{3.9}
\end{equation*}
$$

We now establish (A2). Let $g(x) \triangleq 2 x-f_{A}(x)$. Since $g^{\prime}(0)=1$ (recall that $G_{1}=\delta$ ) $g$ has an analytic inverse $h(x) \triangleq \sum_{n=1}^{\infty} \alpha_{n} x^{n}$ near 0 . We claim that $f_{B}(x) \leq h(x)$ and thus $\rho_{B} \geq \operatorname{Rad} h(\cdot)$. The coeficients $\alpha_{n}$ are given by formula (3.7): $\alpha_{1}=1$ and for $n>1$

$$
\begin{equation*}
\alpha_{n}=\sum_{k=2}^{n}\left\{\sum_{\substack{i_{1}, \ldots, i_{k} \geq 1 \\ i_{1}+\ldots+i_{k}=-\infty}}\right\}\left\|a_{k}\right\| \alpha_{i_{2}} \cdots \alpha_{i_{k}} \tag{3.10}
\end{equation*}
$$

By induction we now show

$$
\begin{equation*}
\left\|b_{n}\right\| \leq \alpha_{n} \tag{3.11}
\end{equation*}
$$

for all $n$. (3.11) is true for $n=1$, suppose (3.11) has been established for $n<m$. Then (3.9), (3.10), and the inductive hypothesis establish (3.11) for $n=m$ and hence for all $n$. Consequently

$$
f_{B}(x)=\sum_{n=m}^{\infty}\left\|b_{n}\right\| x^{n} \leq \sum_{n=1}^{\infty} \alpha_{n} x^{n}=h(x)
$$

which proves our claim above that the measures $b_{n}$ do satisfy assumption (A2) and hence are the kernels of a Volterra series operator which we naturally enough call B. From the formula (3.8) for $b_{n}$ we conclude

$$
A B=I
$$

$B$ is thus a right inverse for $A$. This concludes the proof for the special case.
General Case: Suppose now that $G_{1}$ is invertible in $B^{1}$. We will use the proof of the special case presented above to prove the general case. Let $b_{1} \in B^{1}$ satisfy $a_{1} * b_{1}=\delta$. Let $A_{\text {lin }}$ be the Volterra series operator with first kernel $a_{1}$ and other kernels zero. $A_{\text {lin }}$ is invertible, with inverse $A_{l i n}^{-1}$ (which has first kernel $b_{1}$ and other kernels zero). Consider the operator $A_{\text {lin }} A^{-1}$ whose Kernels we could easily compute with the composition theorem. Its first kernel is $\delta$, so using the construction above find a local right inverse $C$ to $A_{\text {liin }}^{-1} A$. Then $B=C A_{\text {liik }}^{-1}$ is the local right inverse of $A$, since

$$
\begin{equation*}
A B=A_{\text {lin }} A_{\text {lin }}^{-1} A C A_{l i \pi}^{-1}=A_{\text {lis }} A_{\text {lin }}^{-1}=I \tag{3.12}
\end{equation*}
$$

Our final task is to show that the right inverse $B$ is also a left inverse for $A$. Since the first kernel of $B$ is invertible (indeed it has inverse $a_{1}$ ) we can find a right inverse $D$ for $B$. Then we have

$$
\begin{equation*}
A=A I=A(B D)=(A B) D=I D=D \tag{3.13}
\end{equation*}
$$

(3.13) and $B D=I$ shows

$$
B A=I
$$

which with (3.12) proves that $B$ really is the local inverse of $A$ at 0 and completes the proof of theorem 3.4.1.O

Remark: If $a_{1} \in \boldsymbol{X}$, the subalgebra of $\mathbf{B}^{\mathbf{1}}$ of those measures lacking singular continuous part, then we have the criterion ${ }^{13}$
$A$ is invertible iff $\inf _{R a t \geq 0}\left|\hat{a}_{1}(\theta)\right|>0$

### 3.4. Dynamical Syatem Example

To illustrate the theorems of this section we now work an example.
Examplea Consider the one-dimensional dynamical system:

$$
\begin{gather*}
\dot{x}=f(x)+g(u)  \tag{3.14a}\\
x(0)=0  \tag{3.14b}\\
y=q(x) \tag{3.14c}
\end{gather*}
$$

Suppose $f, g$ and $q$ are analytic near $0, f(0)=g(0)=q(0)=0$, and $f^{\prime}(0)<0$. Then the system is exponentially stable at 0 , and for $\|u\|$ small there is a unique state trajectory $z$ satisfying (3.14).

We will now show that the I/O map : $u \rightarrow y$ is a Volterra series operator.
Prooft We first use a loop tranaformation to reexpress equations (3.14a) and (3.14b) in terms of Volterra series operators. (3.14a) and (3.14b) are equivalent to

$$
z=e^{f^{\prime}(0) t} *\left(f_{\operatorname{sxu}}(x)+g(u)\right)
$$

where $f_{s m}(x) \triangleq f(x)-f^{\prime}(0) x$ (the strictly nonlinear part of $f$ ). (See figure (2)). Let $H_{\text {lin }}$ be the Volterra series operator with first kernel $1(\tau) e^{f^{\prime}(0)}$ and other kernels 0 . Let $F_{\text {sul }}, G$, and $\mathbb{Q}$ be the memoryless Volterra series operators associated with the functions $f$ ont, $g$, and $q$, respectively, e.g. $Q_{n}\left(\tau_{1}, \ldots, \tau_{n}\right)=n!^{-1} q^{(n)}(0) \delta\left(\tau_{1}\right) \ldots$.. ( $\left.\tau_{n}\right)$. Then the system equations (3.14) are equivalent to

$$
\begin{gather*}
x=H_{l i n}\left(F_{\text {sun }}(x)+G(u)\right)  \tag{3.15a}\\
y=Q(x) \tag{3.15b}
\end{gather*}
$$

Since $\boldsymbol{H}_{\text {lin }}$ is linear

$$
\begin{equation*}
\left(I-H_{\text {lin }} F_{\text {sux }}\right) x=H_{\text {lin }} G u \tag{3.16}
\end{equation*}
$$

By the sum and composition theorems ( $I-H_{\text {lin }} F_{\text {sut }}$ ) is a Volterra series operator with first kernel $\delta$. By the inversion theorem ( $I-H_{\text {lin }} F_{\text {sul }}$ ) has a Volterra series local inverse near $0\left(I-H_{\text {lin }} F_{s a l}\right)^{-1}$. Since as mentioned above (3.16) has only one solution $x$ when $\|u\|$ is small, it must be

$$
\begin{equation*}
x=\left(I-F_{s u l} H_{l i n}\right)^{-1} G u \tag{3.17}
\end{equation*}
$$

Thus for $\|u\|$ small, the ontput $y$ is given by a Volterra series operator in $u$ :

$$
\begin{equation*}
y=Q\left(I-F_{\text {cul }} H_{\text {lin }}\right)^{-1} G u \tag{3.18}
\end{equation*}
$$

A few comments are in order. (3.14) may have multiple equilibria when $u=0$ (for example if $f(x)=-\sin x$ ), or even a finite escape time for some $u$ 's (for example if $f(x)=-x+x^{2}$ ). We've shown that as long as $\|u\|$ is small enough, say less than $K$, then the state $a$ and the output $y$ are given by a Volterra series in $u$. In particular $\|u\|<K$ must teep the state $a$ from leaving the domain of attraction of 0 , for otherwise the Steady State theorem (see §4.1) or the Gain Bound theorem would be violated.

## 4. Frequency Domaln Topics

In this section we consider frequency domain topics, concentrating on the simplest case: periodic inputs. Even in this case the analysis is not simple. Nevertheless we show that an intuitive formula for the output spectrum in terms of the input spectrum holds in essentially all engineering contexts.

Before starting our topic proper, we prove:

### 4.1. The Steady State Theorem

Theoram 4.1.1 (Steady State theorem): Let $u$ and $u_{s}$ be any signals with $\|u\|,\left\|u_{s}\right\|<\rho=\operatorname{Rad} N$, and suppose that as $t \rightarrow \infty u(t) \rightarrow u_{s}(t)$
Then $N u(t) \rightarrow N u_{s}(t)$ as $t \rightarrow \infty$.
This is a very different concept from $N$ 's being continuous as a map from $L^{\infty} \rightarrow L^{\infty}$, which tells us e.g. that if $u_{n} \rightarrow u$ uniformily as $n \rightarrow \infty$, then $N u_{n} \rightarrow N u$ (uniformly).*
Prooft Suppose $\|u\|,\left\|u_{s}\right\|<\rho$ and $u(t) \rightarrow u_{s}(t)$ as $t \rightarrow \infty$. Let $v=u_{z}-u$ so $v(t) \rightarrow 0$ as $t \rightarrow \infty$. The proof is a modification of the proof of the incremental gain theorem, we simply break the

[^2]$$
O^{\circ} 0-\left(z / y^{\prime} j\right)^{z} I+\left(z / y^{\prime} \cdot j\right)^{l} I=(j) n N-(j)^{s} n N
$$

әЈәपм

$$
\left.\infty \leftarrow I-1 \quad \text { \& } \quad 0 \leftarrow\left(I^{\prime}\right\}\right)^{\mathrm{t}} I
$$

$$
(\|n \mid\|) \delta-\left(\left[x^{4} x-1\right]\|a\|+\|n\|\right) \delta=
$$

saqJ

2лачм

$$
\left(L^{4} j\right)^{2} I+\left(L^{4} t\right)^{t} I=(1)\left(n_{N}-(a+n) N\right)=(g)\left(n_{N}-{ }^{8} n_{N}\right)
$$

Remark: unlike linear systems, the rate of convergence can depend on the amplitude of the input. For example, consider $\boldsymbol{N}$ given by

$$
N_{u}=\sum_{k=4}^{\infty} u(t-k)^{t}
$$

$N$ has radius of convergence one. Now consider step inputs of amplitude $\alpha, 0<\alpha<1$. As $\alpha$ increases to one, the time to convergence to within, say, $1 \%$ of the steady state grows like (1- $\alpha)^{-1}$. For linear systems the time to convergence is independent of the amplitude of the input.

Although in the Steady State theorem $u_{s}$ can be any signal with $\left\|u_{i}\right\|<\rho$, usually $u_{i}$ has the interpretation of a steady state input, for example in

Theorem 4.1.2 (Periodic Steady State theorem)s If the input $u$ is periodic with period $T$ for $t \geq 0$ then the output $N u$ approaches a steady state, also periodic with period $T$. (Soon we'll compute the Fourier Series coefficients of Nu ).

Prooft Let $u_{s}$ be $u$ extended periodically to $t=-\infty$. Clearly $u(t) \rightarrow u_{t}(t)$ as $t \rightarrow \infty$ (indeed $u(t)=u_{s}(t)$ for $t \geq 0$ ) so by the Steady State theorem $N u(t) \rightarrow N u_{s}(t)$ as $t \rightarrow \infty$. $N u_{t}$ is periodic with period $T$ since

$$
\left(N u_{s}(\cdot)\right)(t+T)=N\left(u _ { s } ( \cdot + T ) \left\{(t)=N u_{s}(t)\right.\right.
$$

where the first equality is due to the time-invariance of $N$ and the second equality is due to the $T$-periodicity of $u_{3} . O$

Note in particular that Volterra series operators cannot generate subharmonics. A related application of the Steady State theorem is:

Theorem 4.1.3 (Almost Perlodic Steady State Theorem)s If the input $u$ is almost periodic for $t \geq 0$ then the output approaches an almost periodic steady state. (we'll compute the frequencies and spectral amplitudes of the output in §A5).

Proof The hypothesis simply means that there is some $u_{\mathrm{f}}$ which is almost periodic and agrees with $u$ for $t \geq 0$. By the Steady State theorem we know $y(t) \rightarrow y_{s}(t) \Delta u_{s}(t)$ so we need only show that Volterra series operators take almost periodic inputs into almost periodic outputs. The proof of this, as well as the formula for the spectral amplitudes of the output, are in §A5. This last topic has been studied by Sandberg. ${ }^{22}$

### 4.2. Frequency Domain Volterra Kernels

As with linear systems, it is often convenient to use the Laplace transforms of the kernels, defined by

$$
H_{n}\left(s_{1}, \ldots, g_{n}\right)=\int \cdots \int h_{3}\left(r_{1} \ldots, \tau_{n}\right) e^{-\left(a_{1} r_{1}+\ldots+s_{n} r_{n}\right)} d \tau_{1} \ldots d \tau_{n}
$$

We call $H_{n}$ the $n$th frequency domain kernel or just ternel of the operator $N$. Since $h_{n} \in B^{n}, H_{n}$ is defined at least in $\overline{C_{+}^{K}}\left(C_{+}^{Z}\right.$ means $\left\{a \mid\right.$ Res $\left._{k}>0\right\}$ ).* $H_{z}$ is symmetric, bounded and uniformly continuous there; it is analytic in $C_{+}^{n}$. We should mention that the unicity theorem for Laplace transforms tells us that two measures in $B^{n}$ are equal $\left(h_{n}=g_{n}\right)$ if and only if their Laplace transforms are equal ( $H_{n}=G_{n}$ ).

The formulas of $\$ 3$ are somewhat simpler in the frequency domain. Using the notational convention that $C_{n}$ denotes the $n$th frequency domain kernel of a Volterra series operator $C$, we have:

Theorem 4.2.1: Suppose $A$ and $B$ are Volterra series operators. Then the frequency domain kernels of $A+B, A \cdot B$ (pointwise product), and $A B$ (composition) are given by:

$$
\begin{gathered}
(A+B)_{n}\left(s_{1}, \ldots, s_{n}\right)=A_{n}\left(s_{1}, \ldots, s_{n}\right)+B_{n}\left(s_{1}, \ldots, s_{n}\right) \\
(A \cdot B)_{n}=\sum_{k=1}^{n-1} A_{k} \vee B_{n-k} \Delta \Omega M M \sum_{k=1}^{n} A_{k}\left(s_{1}, \ldots, s_{k}\right) B_{n-k}\left(s_{k+1}, \ldots, s_{n}\right) \\
(A B)_{n}\left(s_{1}, \ldots, s_{n}\right)=S Y M \sum_{k=1}^{n}\left\{\sum _ { \substack { i _ { n } , \ldots , i _ { k } \geq 1 \\
i _ { 2 } + \ldots + i _ { k } = 1 } } A _ { k } \left(s_{2}+\ldots+s_{\left.i_{1}, \ldots, s_{n-i_{k}+1}+\ldots+s_{n}\right)} .\right.\right. \\
\cdot B_{i_{1}}\left(s_{1}, \ldots, s_{i_{1}}\right) \cdots B_{i_{k}}\left(s_{\left.n-i_{k}+1, \ldots, s_{n}\right)}\right.
\end{gathered}
$$

These well-known formulas follow easily from the formulas of $\$ 3$.

### 4.3. Multitone Inputas the Fundamental Frequency Domain Formula

We start with a simple calculation. Suppose that $u(t)$ is a trigonometric polynomial, that is

$$
u(t)=\sum_{k=-M}^{M} \alpha_{k} e^{j w t t}
$$

where $\alpha_{-k}=\bar{\alpha}_{k}{ }^{*}$. Suppose also that $\|u\|<\rho=\operatorname{Rad} N$. Then

$$
\begin{align*}
& y(t)=N u(t)=\sum_{n=1}^{\infty} \int \cdots \int h_{n}\left(\tau_{1}, \ldots, \tau_{n}\right) \prod_{i=1}^{n} \sum_{=-N}^{M} \alpha_{k} e^{j \omega\left(t-r_{i}\right)} d \tau_{i}  \tag{4.5a}\\
& =\sum_{n=\{ }^{\infty}\left\{\sum_{1-N \leq k_{1} \ldots, k_{3} \leq M}\right\} \alpha_{k_{2}} \ldots \alpha_{k_{n}} H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right) e^{j\left(\omega k_{1}+\ldots+\omega k_{n}\right) t} \tag{4.5b}
\end{align*}
$$

The term $\alpha_{k_{1}} \ldots \alpha_{k_{n}} H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right) e^{j\left(\omega k_{1}+\ldots+\omega k_{n}\right) t}$ is often called an $n$th order $\left(\omega k_{1}, \ldots, \omega k_{n}\right)$ intermodulation product. Since it is proportional to $H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)$ this suggests the interpretation
-The Laplace tranaforms of the triongular kernels are called the reguler tranefer fonections of the operator. ${ }^{23}$ -Thus a is real. Complex sigaale are easily handled bat less usefal in the stedy of Volterra series operatora than linear operators.
of $H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)$ as a measure of the $\left(\omega k_{1}, \ldots, \omega k_{n}\right)$ intermodulation distortion of $N$.
Now we've already seen that the first sum in (4.5b) is an honest $l^{1}$ sum, in fact for each $t$,

$$
\sum_{n=\infty}^{\infty}\left|\left\{-N \leq k_{1} \sum_{1,-m k_{8} \leq M}\right\}^{\alpha_{k_{2}} \ldots \alpha_{k_{1}} H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right) e^{j\left(\omega k_{1}+\ldots+\Delta k_{n}\right) t}}\right| \leq f(\|u\|)
$$

where $f$ is the gain bound function of $N$. Consequently we may evaluate the $n$th Fourier coefficient of $y$

$$
\hat{y}(m) \Delta \frac{\omega}{2 \pi} \int_{0}^{\frac{2 \pi}{\omega}} y(t) e^{-j \omega m t} d t
$$

inside the first sum in (4.5b) as:

$$
\hat{y}(m)=\sum_{n=1}^{\infty} \frac{\omega}{2 \pi} \int_{0}^{\frac{2 \pi}{\omega}}\left\{\sum_{-N \leq k_{1} m, k_{2} \leq N}\right\} \alpha_{k_{2} \ldots \alpha_{k_{n}}} H_{\pi}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right) e^{j\left(\omega k_{1}+\ldots+\omega k_{1}\right) t} e^{-j \omega m t} d t
$$

Each integral is easily evaluated (the integrands are trigonometric polynomialg) yielding

$$
\begin{equation*}
\hat{y}(m)=\sum_{n=1}^{\infty}\left\{\sum_{t_{1}+\ldots+k_{1}-m}\right\} \hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right) H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right) \tag{4.6}
\end{equation*}
$$

since $\hat{u}(k)=\alpha_{k}$ for $|k| \leq M$ and 0 for $|k|>M$ (and thus the inger sum in (4.6) is finite). We call (4.6) the fundamental frequency domain formula since it expresses the outpat spectrum in terms of the input spectrum. Of course we've only established it for inputs which are trigonometric polynomials, but we will see that it is true for more general periodic inputs, and an analogous formula holds for almost periodic inputs as well (see § A5).

Remark: Suppose a trigonometric polynomial signal $u$ is passed through a unit $n$th power law device so that $y(t)=u(t)^{n}$. Then

$$
\hat{y}(m)=\hat{u} \hat{u}^{\circ n}(m)=\left\{\sum_{k_{2}+\ldots+k_{2}=m}\right\}^{\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right)}
$$

where $\hat{u}^{\text {m }}$ means the $n$-fold convolution $\hat{u} \neq \hat{u} * \ldots * \hat{\imath}$ (the sum in the convolution is finite here!). The first equality makes sense: it is just the dual of the correspondence between convolution in the time domain and multiplication in the frequency domain. The second equality makes the fundamental formula (4.6) seem quite natural; the $n$th term of (4.6) can be thought of as an $n$-fold convolution power of $\hat{u}$, weighted by $H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)$.

Before establishing the fundamental formula for more general periodic inputs, we have to carefully examine the question of whether it even makes sense for more general periodic inputs. Despite its resemblance to the composition formula and the fact that every sum and integral
encountered so far has converged absolutely, we have:

### 4.4. SURPRISE! Fundamental Formula Doenn't Converge Abeolutely

Remarkably the fundamental formula is not absolutely convergent even for $u$ as simple as a two-tone input signall That is

$$
\sum_{n=1}^{\infty}\left\{\sum_{k_{1}+\ldots+k_{n}-m}\right\}^{\left|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right) H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)\right|}
$$

can equal $\infty$ even in the case considered above, $u$ a trigonometric polynomial (but our calculation was correct).

Remark: Practically, this means that we cannot arbitrarily rearrange the terms in the sum above. We must first perform the inner (bracketed) sum (which in this case is a finite sum), and then perform the outer sum over $n$.

Examples Let $u=\frac{5}{9}(\cos t+\sin 2 t)$. Then $\|u\|$ can be shown to be

$$
\frac{5}{9}\left(\frac{15+\sqrt{33}}{32}\right)^{1 / 2}\left(\frac{3+\sqrt{33}}{4}\right)
$$

which is about $0.978<1$. Let $N$ be the memoryless operator with $H_{n}=1$ for all $n$, that is $y(t)=u(t) /(1-u(t))$. Then $\rho=1$ so $y(t)$ makes sense and satisfies $\|y\| \leq\|u\| /(1-\|u\|)$ (which is about 45). According to the fundamental formula (4.6) of the last subsection, the D.C. term of $y$ is given by:

$$
\begin{equation*}
\hat{y}(0)=\sum_{n=1}^{\infty}\left\{\sum_{k_{2}+\ldots+k_{2}=0}\right\}^{\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right)} \tag{4.7}
\end{equation*}
$$

Now we claim that (4.7) does not converge absolutely. To see this,

$$
\begin{aligned}
& \sum_{n=m}^{\infty}\left\{\sum_{\left\{k_{1}+\ldots+k_{n}=0\right.}\right\}\left|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right)\right| \geq \sum_{n}\left\{\sum_{\operatorname{ven}\left(k_{2}+\ldots+k_{2}=0\right.}\right\}\left|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right)\right| \\
& =\sum_{n}\left\{\sum_{\operatorname{coven}\left\{k_{1}+\ldots+k_{1}=0\right\}}\right\} \hat{v}\left(k_{1}\right) \ldots \hat{v}\left(k_{n}\right)
\end{aligned}
$$

where $v(t) \triangleq \frac{5}{9}(\cos t+\cos 2 t)$ so that $|\hat{u}(k)|=\hat{v}(k)$ for all $k$.

$$
=\sum_{n=v o s} \frac{1}{2 \pi} \int_{0}^{2 \pi} v(t)^{n} d t \geq \sum_{n=v e n} \frac{1}{4 \pi}=\infty
$$

since $v(t) \geq 1$ for $-.25 \leq t \leq .25$. Thus the fundamental formula isn't absolutely convergent in this simple case.

It is surprising that the trouble in (4.6) occurs when the input is a simple trigonometric polynomial signal; we might expect it to give us trouble only when, say, $u$ does not have an absoJutely convergent Fourier series.

There is one obvious but rare case in which (4.6) does converge absolutely. Suppose $\hat{\boldsymbol{u}} \in \boldsymbol{l}^{\mathbf{1}}$, i.e. $u$ has an absolutely convergent Fourier series, and in addition $f\left(\|\hat{u}\|_{1}\right)<\infty$. Then $|\hat{u}| \in \boldsymbol{l}^{\boldsymbol{l}}$ and $|\hat{u}|^{\text {mn }} \in l^{2}$ with $\left\|\left.\hat{u}\right|^{* \pi}\right\|_{1} \leq\|\hat{u}\|_{1}^{n}$, thus we have the estimate

$$
\sum_{n=1}^{\infty}\left\{\sum_{k_{2}+\ldots+k_{n}=m}\right\}\left\|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right) H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)\right\| \leq \sum_{n=1}^{\infty}\|\hat{u}\| \hat{i}\left\|h_{n}\right\|=f\left(\|\hat{u}\|_{1}\right)
$$

In conclusion, then, we must proceed with extreme care in establishing the fundamental formula for more general periodic input signals.

### 4.5. Proof of Fundamental Formula for Gencral Inputs

We start with some calculations. Suppose $u$ is any periodic input with $\|u\|<p$. Recall that the $M$ th Cesaro sum of the Fourier series of $u$ is defined by

$$
u_{M}(t)=\sum_{k=M}^{M}\left(1-\frac{|k|}{M}\right) \hat{u}(k) e^{j \omega k t} \Delta \sum_{k} C_{M}(k) \hat{u}(k) e^{j \omega k t}
$$

$u_{M}$ is $u$ convolved with an approximate identity and thus satisfies $\left\|u_{M}\right\| \leq\|u\|$ and $\left\|u_{M^{-}} u\right\|_{1} \rightarrow 0$ as $M \rightarrow \infty$. 24 From the first fact we conclude that $N u_{M}$ makes sense since $\left\|u_{M}\right\| \leq\|u\|<\rho=\operatorname{Rad} N$. Using the Incremental Gain theorem for $L^{1}$ (theorem 2.3.5), we conclude that $\left\|N u-N u_{M}\right\|_{1} \rightarrow 0$ as $M \rightarrow \infty$. Hence $\widehat{N u_{M}}=\hat{y}_{M}$ converges uniformly to $\hat{y}$ as $M \rightarrow \infty$. $u_{M}$ is a trigonometric polynomial so we know the fundamental formula holds for $N u_{M} ;$ putting all this together we have shown

$$
\begin{align*}
& \hat{y}(m)=\lim _{N \rightarrow \infty} \sum_{n=1}^{\infty}\left\{\sum_{k_{1}+\ldots+k_{n}=m}\right\} \hat{u}_{M}\left(k_{1}\right) \ldots \hat{u}_{M}\left(k_{n}\right) H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)  \tag{4.8}\\
& =\sum_{n=1}^{\infty} \lim _{N \rightarrow \infty}\left\{\sum_{\left.k_{2}+\ldots+k_{3}=m\right\}} \mid \hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right) \prod_{i=1}^{n} C_{M}\left(k_{i}\right) H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)\right. \tag{4.9}
\end{align*}
$$

The dominated convergence theorem justifies the interchange of limit and sum in (4.8) since as we have mentioned before the first sum in (4.8) and (4.9) is always absolutely convergent and $\left|C_{M}\right| \leq 1$. Since $\lim _{M \rightarrow \infty} C_{M}(k)=1$ for each $k$, if we knew that the inner sum also converged absolutely we could apply dominated convergence once again to conclude

$$
\begin{equation*}
=\sum_{n=1}^{\infty}\left\{\sum_{k_{1}+\ldots+k_{n}=m}\right\} \hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right) H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right) \tag{4.10}
\end{equation*}
$$

which would establish the fundamental formula in the general case.

Unfortunately the inner sum

$$
\begin{equation*}
\left\{\sum_{\left\{k_{1}+\ldots+k_{n}=m\right.}\right\}^{\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right) H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)} \tag{4.11}
\end{equation*}
$$

is not always absolutely convergent (and thus does not always make sense). In such a case formula (4.9) is as close as we can get to the fundamental formula. But in fact the inner sum is absolutely convergent in almost all situations arising in engineering. We now present two conditions which suffice:

Lemma 4.5.1: Suppose $u$ has bounded variation over one period. Then

$$
\left\{\sum_{z_{1}+\ldots+k_{a}=m}\right\}\left|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right)\right|<\infty
$$

In particular, the inner sum (4.11) in the fundamental formula converges absolutely. The proof is given in §A4.
Lemma 4.5.2: Suppose that $H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)=O\left(\frac{1}{k_{1} \ldots k_{n}}\right)$. Then the inner sum (4.11) is absolutely convergent.

Remark: This condition can be interpreted as: $N$ is strictly proper. For example the kernels of the input/output operator of a dynamical system with vector field affine in the input have this property.

The proof is in §A4. We summarize the results of this section in
Theorem 4.5.3 (Fundamental Frequency Domain Formula)z Suppose $\|u\|<\rho$ and that either
(I) the input $u$ has bounded variation over one period, or
(II) the operator $N$ is strictly proper, that is, $H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)=O\left(\frac{1}{k_{1} \ldots k_{n}}\right)$.

Then the fundamental frequency domain formula is valid, that is:

$$
\hat{y}(m)=\sum_{n=1}^{\infty}\left\{\sum_{k_{1}+\ldots+k_{2}=m}\right\}^{\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right) H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)}
$$

Proon Theorem 4.5.3 follows from the discussion at the beginning of this section and the lemmas above. O

## A1. Volterra-Llke Serles

In the study of (linear) convolution operators in engineering it is common to consider only a subalgebra of the bounded measures, for example the subalgebra of measures lacking singular continuous part. ${ }^{1 s}$ This algebra is large enough to capture all of the commonly occuring distributed systems such as distributed transmission lines, transport delays in control systems, etc. Similarly in the study of Volterra series operators only certain types of measures occur in practice; the singular kernel $1\left(\tau_{1}\right) 1\left(\tau_{2}\right) e^{-\tau_{1}} \delta\left(\tau_{1}-\tau_{2}\right)$ of example 2 of $\mathbf{\$ 2 . 1}$ is typical. Sandberg calls series with kernels of this form Volterra-Like; ${ }^{6}$ the idea occurs as early as 1953 in L. Zadeh's paper. ${ }^{25}$

In a Volterra-like series we index the series not by the order $n$ but by a multi-index $\vec{n}=\left(n_{1}, \ldots n_{k}\right) \quad\left(n_{j}>0\right) . \quad k$ is called the length of $\vec{n}$; the degree of $\vec{n}$ is defined by $\partial \vec{n}=n_{1}+\ldots+n_{k}$.

$$
\begin{gathered}
N u(t)=\sum_{\mathbb{Z}} y_{\pi}(t) \\
y_{\pi}(t)=\int \cdots \int h_{\pi}\left(\tau_{1} \ldots \tau_{k}\right) u\left(t-\tau_{1}\right)^{n_{1}} \ldots u\left(t-\tau_{k}\right)^{n_{1}} d \tau_{1} \ldots d \tau_{k}
\end{gathered}
$$

where now the kernels $h_{R}$ are ordinary $L^{1}$ functions instead of bounded measures. Each Volterra-like kernel $h_{\boldsymbol{T}}$ can be turned into an equivalent Volterra kernel $h_{[n]}$ by:

$$
h_{\mathrm{Rm}}\left(\tau_{1}, \ldots \tau_{k}\right) \triangleq \mathbf{S Y M} h_{n}\left(\tau_{1}, \tau_{n_{2}+1}+\ldots . \tau_{n-n_{k}+1}\right) d\left(\tau_{1}-\tau_{2}\right) \ldots d\left(\tau_{n_{1}-1}-\tau_{n_{2}}\right) \ldots d\left(\tau_{n-1}-\tau_{n}\right)
$$

We call $h_{\text {俩 }}$ the associated Volterra kernel of the Volterra-like kernel $h_{B}$. Collecting the associated Volterra kernels by degree

$$
\begin{equation*}
h_{n}=\sum_{\partial \pi=m} h_{[(\pi)} \tag{A1.1}
\end{equation*}
$$

yields a Volterra series equivalent to the Volterra-like series. Via this associated Volterra series, Volterra-like series inherit the concepts of gain bound function and radius of convergence.

Note that $h_{\text {ma }}$ is supported on the $k$-dimensional set given by*

$$
C_{\pi}=\left\{\left(\tau_{1}, \ldots \tau_{n}\right)^{T} \mid n_{1} \text { of the } \tau^{\prime} \mathrm{s} \text { are } x_{1}, \cdots n_{k} \text { of the } \tau^{\prime} \mathrm{B} \text { are } x_{k}\right\}
$$

Thus the associated kernel is singular (with respect to Lebesgue measure) unless $\vec{n}=(1, \ldots 1)$.

[^3]We extend the notion of SYM to Volterra-like series by:

$$
\operatorname{SYM} h_{\pi}\left(\tau_{1}, \ldots \tau_{k}\right)=\frac{1}{k!} \sum_{\sigma c S^{t}} h_{\sigma \pi}\left(\tau_{\sigma 1} \ldots \ldots \tau_{\sigma k}\right)
$$

where $\sigma \vec{n}=\left(n_{\sigma 1}, \ldots n_{\sigma t}\right)$; we say $h_{\pi}$ is symmetric if $S Y M h_{\pi}=h_{\pi}$. This agrees with our earlier notation if we think of the old order $n$ as the $n$-long multi-index $(1, \ldots 1)$, since $\sigma(1, \ldots 1)=(1, \ldots 1)$. Note that SYM $h_{z}$ involves not just the Volterra-like kernel $h_{\nabla}$ but all Volterra-like kernels of the form $\overrightarrow{\boldsymbol{m}}=\sigma \vec{n}$. We say $\vec{m}$ and $\vec{n}$ have the same type in this case. A Volterra-like series thus has $\mathbf{P}(n)$ different types of kernels of degree $n$, where $\mathbf{P}(n)$ is the number of partitions of $n$.** If the Volterra-like series is symmetric then the kernels of the same type have identical associated kernels and are simply related by:

$$
h_{m}\left(\tau_{2}, \ldots \tau_{k}\right)=h_{\sigma \pi}\left(\tau_{1}, \ldots \tau_{k}\right)=h_{\pi}\left(\tau_{\sigma 1}, \ldots \tau_{\sigma k}\right)
$$

This exteasion of SYM will also be useful in the study of multi-input Volterra series.

## Theorem A1.1 (Uniquenesa theorem for Volterra-Like serles):

Suppose $N$ and $M$ are Volterra-Like series operators with kernels $h_{\pi}$ and $g_{\pi}$, respectively. Then

Proort The "ir" part is clear. By the Uniqueness theorem (theorem 2.5.2) we know $h_{n}=g_{n}$, where $h_{n}$ and $g_{n}$ are the kernels of the associated Volterra series (given in (A1.1) above). We will finish the proof by showing that $h_{n}$ determines the Volterra-like kernels SYM $h_{\mathbf{m}}$.

## Theorem A1.2 (Decomposition theorem for Volterra-Like series):

Suppose $h_{n}$ are the kernels of the Volterra series associated with a Volterra-like series with kernels $h_{\mathbf{z}}$. Then $h_{\mathbf{s}}$ uniquely determines the Volterra-like kernels SYM $h_{\mathbf{x}}$.

Thus if a Volterra series comes from a Volterra-like series, then each kernel can be uniquely decomposed into the $2^{n-1}$ symmetric Volterra-like kernels with which it is associated. Another way to think of the Decomposition theorem is: the (linear) map of the symmetric Volterra-like kernels into the associated Volterra kernels (given by formula (A1.1)) is injective.

Before starting the proof, let us consider a simple example which illustrates the idea. The second kernel of the associated Volterra series is:

$$
h_{2}\left(r_{1}, r_{2}\right)=h_{\{(1,1\rangle}+h_{\{(2)\rangle}=h_{(1,1)}\left(\tau_{1}, \tau_{2}\right)+\frac{1}{2} h_{(2)}\left(\tau_{1}\right) \delta\left(\tau_{1}-\tau_{2}\right)+\frac{1}{2} h_{(2)}\left(\tau_{2}\right) \delta\left(\tau_{1}-r_{2}\right)
$$

Decomposing $h_{2}$ is easy: the terms $h_{\{(2)\}}$ and $h_{\left(L_{1}, 1\right)}$ are mutually singular measures (The first is supported on the line $\left\{\tau_{1}=\tau_{2}\right\}$ and the second is absolutely continuous). To be quite explicit we e*There is no nice formula for $P(n)$. For those interested it is asymptotic to $(4 \sqrt{3} \pi)^{-1} \exp \pi \sqrt{2 n / 3}$.
have the formulas:

$$
\begin{aligned}
& h_{(1,1)}\left(r_{1}, T_{2}\right)=h_{2}\left(\tau_{1}, T_{2}\right) \text { for } T_{1} \neq \tau_{2} \\
& h_{(2)}(\tau)=\lim _{i \rightarrow 0} \frac{1}{2 \sqrt{2 \varepsilon}} \int_{r=1}^{r+c} \int_{r=c} h_{2}\left(r_{1}, r_{2}\right) d r_{1} d \tau_{2}
\end{aligned}
$$

The proof of the Decomposition theorem uses the same idea: the associated kernels of $h_{\pi}$ and $h_{m}$ are mutually singular unless $\vec{n}$ and $\vec{m}$ are of the same type. To prove this, note that the associated kernel of $k_{x}$ has all its mass in the set

$$
C_{\mathrm{z}}^{0}=\left\{\left(\tau_{1}, \ldots \tau_{\mathrm{n}}\right)^{\tau} \mid n_{1} \text { of the } \tau^{\prime} \mathrm{s} \text { are } x_{1}, \ldots n_{k} \text { of the } \tau^{\prime} \mathrm{s} \text { are } x_{k} ; x_{i} \text { are distinct }\right\}
$$

This is no more than the assertion that

$$
\int \cdots \int h_{\pi}\left(\tau_{1}, \ldots \tau_{k}\right) u\left(t-\tau_{1}\right)^{n_{1}} \ldots u\left(t-\tau_{k}\right)^{\pi_{k}} d \tau_{1} \ldots d \tau_{t}=\int_{r_{i}} \cdots \iint_{\text {detma }} h_{8}\left(r_{1} \ldots \tau_{k}\right) u\left(t-\tau_{1}\right)^{n_{1}} \ldots u\left(t-\tau_{k}\right)^{\pi_{k}} d \tau_{1} \ldots d \tau_{k}
$$

(remember that $h_{7}$ is an $L^{2}$ function).
The sets $C_{\overrightarrow{\boldsymbol{n}}}^{0}$ and $C_{\dot{\boldsymbol{m}}}^{0}$ are disjoint if $\vec{n}$ and $\vec{m}$ are of different type, and equal if the types are the same. This establishes the claim that the associated kernels are mutually singular unless the multi-indices are of the same type. The $L^{1}$ function $h_{\pi}\left(\tau_{1}, \ldots, \tau_{k}\right)$ is determined by the integrals

$$
\begin{equation*}
\int \cdots \int h_{\mathrm{k}}\left(\tau_{1}, \ldots, \tau_{k}\right) u_{1}\left(\tau_{1}\right) \ldots u_{k}\left(\tau_{k}\right) d \tau_{1} \ldots d \tau_{k} \tag{A1.2}
\end{equation*}
$$

where the $u_{i}, i=1, \ldots, k$ are in $L^{\infty}$. According to the discussion above we have

$$
\begin{gathered}
\int \cdots \int h_{n}\left(r_{1} \ldots, r_{n}\right) u_{1}\left(\tau_{1}\right) \ldots u_{1}\left(\tau_{\text {nex }}\right) u_{2}\left(\tau_{n_{1}}+\frac{1}{}\right) \ldots u_{k}\left(r_{n}\right) d \tau_{1} \ldots d \tau_{n} \\
\quad=K \int \cdots \int h_{R}\left(r_{1}, \ldots, r_{k}\right) u_{1}\left(r_{1}\right) \ldots u_{k}\left(r_{k}\right) d \tau_{1} \ldots d \tau_{k}
\end{gathered}
$$

where $K$ is the number of Volterra-like kernels with the same type as $\vec{n}$. Thus the integrals (A1.2), and hence the function $h_{\pi}$, are determined by $h_{n}$. This proves the Decomposition theorem.

Remark: The Decomposition theorem is not so obvious as it might seem. For example consider the consequence that (nonzero) operators of the form

$$
y(t)=\iint h_{\left(2_{2}\right)}\left(\tau_{1}, \tau_{2}\right) u\left(t-\tau_{1}\right)^{2} u\left(t-\tau_{2}\right)^{2} d \tau_{1} d \tau_{2}
$$

can never be put in the form

$$
y(t)=\iint h_{(1,8)}\left(\tau_{1}, \tau_{2}\right) u\left(t-\tau_{1}\right) u\left(t-\tau_{2}\right)^{3} d \tau_{1} d \tau_{2}
$$

This is so even though the associated kernels are both supported on two-dimensional sets. The frequency domain version of the example above is: Suppose $H_{(2,2)}\left(\varepsilon_{1}, s_{2}\right)$ and $H_{(1, s)}\left(\varepsilon_{1}, s_{2}\right)$ are the

Laplace transforms of symmetric fanctions in $L^{1}\left(R_{+}^{2}\right)$. The Decomposition theorem says we can extract $H_{(2,2)}$ and $H_{(1, s)}$ from the scasth order frequency domain kernel

$$
H_{4}\left(s_{1}, \ldots \varepsilon_{4}\right)=\operatorname{SYM}\left\{H_{(2,2)}\left(\theta_{1}+s_{2}, \varepsilon_{3}+s_{4}\right)+H_{\left(1, s^{3}\right)}\left(\theta_{1}, s_{2}+\delta_{3}+s_{4}\right)\right\}
$$

(which has nine terms!) There are explicit formulas which effect this decomposition, but we will not give them here.

Corollary A1.3s If $h_{\boldsymbol{z}}$ are symmetric, then

$$
\left\|h_{\mathrm{s}}\right\|=\sum_{\partial X=\mathrm{x}}\left\|h_{\mathrm{R}}\right\|
$$

Thus the gain bound function, which we originally defined via the associated Volterra series, is simply given by:

$$
f(x)=\sum_{\pi}\left\|h_{\pi}\right\| x^{\partial \pi}
$$

## A2. Incremental Gain Theorem for $L^{\text {p }}$

To demonstrate the difficulty of a theory of Volterra series operators for $L^{p}, p<\infty$, which is unadulterated by reference to $\|u\|_{\infty}$ consider just the memoryless operator $N u(t)=f(u(t))$. If $N$ is to be defined on any open subset of $L^{p}$ then we must have $\operatorname{Rad} N=\rho=\infty$. It is not hard to show that $N$ maps $L^{p}$ back into $L^{p}$ if and only if $f$ is sector bounded, i.e. $|f(x)| \leq K|x|$. Sandberg has recently shown that if $N$ has a Frechet derivative at 0 (as an operator from $L^{p}$ into $L^{\text {p }}$ ) then $f$ is in fact linear ${ }^{22}$

We now give the proof of

## lemma 2.3.48

$$
\|N(u+v)-N u\|_{p} \leq\|v\|_{p} \frac{f(\|u\|+\|v\|)-f(\|u\|)}{\|v\|} \leq\|v\|_{P} f^{\prime}(\|u\|+\|v\|)
$$

(Remember that unmarked norms are $\infty$-norms).
Proof The conclusion is, if anything, sharpened, if we assume the kernels are symmetric (see §2.5) so we will assume they are. Then:

$$
\begin{gathered}
(N(u+v)-N u)(t)=\sum_{n=1}^{\infty} \int \cdots \int h_{n}\left(\tau_{1}, \ldots, \tau_{n}\right)\left\{\prod_{i=1}^{n}(u+v)\left(t-r_{i}\right)-\prod_{i=1}^{n} u\left(t-\tau_{i}\right)\right\} d \tau_{1} \ldots d \tau_{n}= \\
=\sum_{n=1}^{\infty} \int \cdots \int h_{n}\left(\tau_{1}, \ldots, r_{n}\right) \sum_{k=1}^{n}\left(\frac{n}{k} \prod_{i=1}^{k} v\left(t-\tau_{i}\right) d \tau_{i} \prod_{i=1}^{n} u\left(t-\tau_{i}\right) d \tau_{i}\right.
\end{gathered}
$$

Thus

$$
\begin{gathered}
|N(u+v)-N u|(t) \leq \\
\leq\left.\sum_{n=1}^{\infty} \sum_{k=1}^{n}\binom{n}{k}\|v\|\right|^{k-1}\|u\|^{n-t} \int\left\{\int \cdots \int\left|h_{n}\left(\tau_{1}, \ldots, \tau_{n}\right)\right| d \tau_{2} \ldots d \tau_{n}\right\}\left|v\left(t-\tau_{1}\right)\right| d \tau_{1}
\end{gathered}
$$

As in theorem 2.3 .4 the bracketed expression is a measure in $r_{1}$ with norm $\left\|h_{n}\right\|$, so we have ${ }^{13}$

$$
\|N(u+v)-N u\|_{p} \leq\|v\|_{p} \sum_{a=1}^{\infty}\left\|h_{a}\right\| \sum_{k=a}^{n}\binom{n}{k}\|v\|^{k-1}\|u\|^{s-k}=\|v\|_{8} \frac{f(\|u\|+\|v\|)-f(\|u\|)}{\|v\|}
$$

The last inequality in the conclusion of lemma 2.3 .4 follows from the mean value theorem.

## A3. Taylor Series Which Aren't Volterra Series

In §2.5 we showed that the Volterra series operators are simply Taylor series of TI operators $: L^{\infty} \rightarrow L^{\infty}$, but noted that the Volterra series are not all of the Taylor series. In this section we discuss this point in more detail.

Much of the theory of Volterra series holds for the more general Taylor series

$$
N u=\sum_{n=1}^{\infty} P_{n}(u)==\sum_{n=1}^{\infty} M_{n}(u, \ldots, u)
$$

where $M_{n}$ is the bounded TI $n$-linear map : $L^{\infty} \rightarrow L^{\infty}$ given by $M_{n}=(n!)^{-1} D^{(n)} N(0)$. With the gain bound function $f(x)=\sum\left\|M_{n}\right\| x^{2}$ only notational changes are required to prove all the results of §3. For example, such an $N$ has a Taylor series inverse near 0 if and only if $M_{1}$ is invertible.

The differences between our formulation of Volterra series and a more general formulation based on Taylor series are:
(I) Not all bounded TI $n$-linear maps : $L^{\infty n} \rightarrow L^{\infty}$ have a convolution representation

$$
\begin{equation*}
M_{n}\left(u_{1}, \ldots u_{n}\right)=\int \cdots \int h_{n}\left(r_{1}, \ldots, \tau_{n}\right) u_{1}\left(t-r_{1}\right) \ldots u_{n}\left(t-r_{n}\right) d r_{1} \ldots d r_{n} \tag{A3.1}
\end{equation*}
$$

with $h_{m} \in B^{n}$.
(II) The norm we use, $\left\|h_{n}\right\|$, is not equivalent to the norm $\left\|\| M a\right.$ on $L_{n}\left(L^{\infty}, L^{\infty}\right)$, it is stronger (larger). That is (with some abuse of notation)

$$
\left\|h_{n}\right\|_{M a} \triangleq \sup _{\left\|u_{i}\right\|<\Omega}\left\|\int \ldots \int h_{n}\left(r_{1}, \ldots, r_{n}\right) u\left(t-r_{1}\right) \ldots u\left(t-r_{n}\right) d r_{2} \ldots d r_{n}\right\| \leq\left\|h_{n}\right\|
$$

and the ratio of the two is not bounded away from zero. Indeed we will give an example where the ratio is zero.
(I) is true even for $n=1$. We now give an example. Consider the subspace of $L^{\infty}$ of those $u$ 's with a limit at $t=-\infty$, that is

$$
\left\{u \in L^{\infty} \mid \lim _{t \rightarrow \infty} u(t) \text { exists }\right\}
$$

On this subspace we define $F(u) \triangleq \lim _{t \rightarrow-\infty} u(t) . F$ is clearly a LTI bounded functional on this subspace. Using the Hahn-Banach theorem and the Axiom of Choice F can be extended to a LTI bounded functional on all of $L^{\infty}$, which we denote $\mathrm{LIM}{ }^{7}{ }^{7} \mathrm{LIM}$ can also be thought of as a bounded LTI operator: $L^{\infty} \rightarrow L^{\infty}$ (though its range is just the constants).

For any $u$ which vanishes for $t<0$ we have LIM $u=0$. This establishes that LIM is causal, and tinat LIM has no representation as a convolution with a measure. It also shows that the Steady State theorem does not hold for LIM. To mention just one more bizarre property of LIM, it is a bounded LTI operator which maps sinusoids to constants!

Clearly this example is absurd from an engineering point of view. LIM's perfect memory of the infinitely remote past (and indeed, total amnesia for the finite past) contradicts our intuition that bounded LTI physical devices and systems should have a decaying memory.*

Let us now give an example of (II). For $n>1 \prod_{i=1}^{n} L I M u_{i}$ furnishes an example of a bounded multilinear operator not given by a convolution as in (A3.1). Less bizarre examples can also be given for $n>1$. For example we can have a convolution representation with $h_{n}$ an unbounded measure.** Consider the kernel

$$
h_{2}\left(\tau_{1}, \tau_{2}\right)=1\left(\tau_{1}\right) 1\left(\tau_{2}\right) \frac{\cos \left(\tau_{1} \tau_{2}\right)}{\left(1+\tau_{2}\right)\left(1+\tau_{2}\right)}
$$

Then $\left\|h_{2}\right\|=\int\left|h_{2}\left(\tau_{1}, \tau_{2}\right)\right| d \tau_{1} d \tau_{2}=\infty$. Nevertheless this kernel induces a bounded bilinear map $: L^{\infty 2} \rightarrow L^{\infty}$. First we have to say what we mean by the convolution since the integral in (A3.1) is not absolutely convergent with this $\boldsymbol{h}_{2}$. We mean

$$
M_{2}\left(u_{1}, u_{2}\right) \Delta \lim _{\tau \rightarrow \infty} \int_{0}^{T} \int_{0}^{T} h_{2}\left(\tau_{1}, \tau_{2}\right) u\left(t-\tau_{1}\right) u\left(t-\tau_{2}\right) d \tau_{1} d \tau_{2}
$$

To see that this limit exists and that $M_{2}$ is bounded, we rewrite this as

$$
\begin{equation*}
=\lim _{\delta \rightarrow \infty} \int_{0}^{\infty}\left\{\frac{u_{2}\left(\tau_{2}\right)}{1+\tau_{2}} 1\left(\tau_{2} \leq T\right)\right\}\left\{\operatorname{Re} \int_{0}^{T} e^{-i \tau_{1} \tau_{2}} \frac{u_{1}\left(\tau_{1}\right)}{1+\tau_{1}} d \tau_{1}\right\} d \tau_{2} \tag{A3.2}
\end{equation*}
$$

As $T \rightarrow \infty$ the lefthand bracketed expression in (A3.2) converges in $\boldsymbol{L}^{2}$ to the $\boldsymbol{L}^{2}$ function $u_{2}\left(\tau_{2}\right) /\left(1+\tau_{2}\right)$; by the Plancherel theorem the righthand bracketed expression in (A3.2) converges in $L^{2}$ to the $L^{2}$ function $\operatorname{Re}\left(u_{1}(\cdot) /(1+(\cdot)) \mid\left(\tau_{2}\right)\right.$. Consequently the limit in (A3.2) exists and is

[^4]bounded by
\[

$$
\begin{gathered}
\left|M_{2}\left(u_{1}, u_{2}\right)(t)\right| \leq\left\|\frac{u_{2}(\cdot)}{1+(\cdot)}\right\|\left\|_{2}\right\| \operatorname{Re}\left(\frac{u_{1}(\cdot)}{1+(\cdot)}\right)\| \|_{2} \\
\leq \frac{2 \sqrt{2 \pi}}{3}\left\|u_{1}\right\|_{\infty}\left\|u_{2}\right\|_{\infty}
\end{gathered}
$$
\]

which establishes $\left\|M_{2}\right\|_{M Z} \leq 2 \sqrt{2 \pi} / 3$. This example was suggested by D. J. Newman. Like the first example LIM above, it is rather forced.

There are thus at least three costs associated with generalizing Volterra Series operators to arbitrary Taylor series:
(1) We lose the concrete convolution representation (A3.1);
(2) The norm $\left\|h_{\mathrm{n}}\right\|=\int \cdots \int\left|h_{n}\right| d r_{1} \ldots d \tau_{n}$ is replaced by $\left\|M_{n}\right\|_{M a}$ which is nearly impossible to compute;
(3) We include clearly nonphysical operators such as LIM.

It is the authors' feeling, and we hope the examples above have convinced the reader, that the mathematical elegance and completeness of a general Taylor series formulation is not worth (1)(3).

## A4. Absolute Convergence of the Inner Sum

In $\S 4.5$ we established the Fundamental Frequency Domain Formula under the hypothesis that

$$
\begin{equation*}
\left\{\sum_{k_{1}+\ldots+k_{n}-m}\left\|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right) H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)\right\|\right. \tag{A4.1}
\end{equation*}
$$

be finite. In this section we give two simple conditions which ensure that (A4.1) is finite, the first a condition on the input signal $u$, and the second a condition on the kernel $H_{n}$.

## A4.1 Conditions on the Input Signal

We seek conditions which ensure that

$$
\begin{equation*}
\left\{\sum_{t_{2}+\ldots+k_{0}=m}\left\|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right)\right\|\right. \tag{A4.2}
\end{equation*}
$$

is inite. This of course implies that (A4.1) is finite, since $\left|H_{n}\right| \leq\left\|h_{n}\right\|$. Note that (A4.2) is simply (A4.1) when $N$ is the simplest possible $n$-order operator: the memoryless $n$-power law device $N u(t)=u(t)^{n}$.

Since $u \in L^{\infty}, u \in L^{2}$, so $\hat{u} \in l^{2}$. Thus for $n=2$ (A4.2) is just a convolution of two sequences in $l^{2}$ and thus is finite by the Cavehy-Sehwarz inequality:

$$
\begin{equation*}
\sum_{k_{1}+k_{2}-m}\left|f\left(k_{1}\right) g\left(k_{2}\right)\right|=\sum_{k=1}^{\infty}|f(k)||g(m-k)| \leq\|f\|_{2}\|g\|_{2} \tag{A4.3}
\end{equation*}
$$

Since the convolution of two $l^{2}$ sequences is not, in general, in $l^{2}$, the finiteness of (A4.2) already is dubious for $n=3$. On the other hand if $\hat{u} \in l^{2}$, then convolution iterates of $u$ make sense and are still in $1^{1}$ : (A4.2) is then bounded by $\|\hat{u}\|_{1}^{2}$.

It is a remarkable fact that for most $\because$ (A4.2) is finite, even when $t$ is not in $l^{1}$. It is not true for all $u \in L^{\infty}, \cos (1 / t)$ (extended periodically) is a counterexample.*

Theorem A4.1.1 Suppose that $\hat{u}(k)=O(1 / k)$. Then (A4.2) is finite, that is

$$
\left\{\sum_{t_{2}+\ldots+k_{1}-m}\right\}^{\mid \hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right) \|<\infty}
$$

Prooft Suppose that $\hat{u}(k)=O(1 / k)$. Then there is a constant $\beta$ such that $|\hat{u}(k)| \leq \beta \hat{v}(k)$ where

$$
\hat{v}(k) \Delta \begin{cases}1 & k=0 \\ 1 /|k| & k \neq 0\end{cases}
$$

Since $\hat{v} \in R^{2}$, it is indeed the Fourier series of some $L^{2}$ fanction which we will call, surprisingly enough, v. In fact

$$
v(t)=1-\log 2-\log (1-\cos t)
$$

the verification of which we will spare the reader.
Now

$$
\begin{equation*}
\left\{\sum_{\left\{k_{2}+\ldots+k_{3}=m\right.}\right\} \mid \hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n} \| \leq \beta^{n}\left\{\sum_{k_{1}+\ldots+k_{4}=m}\right\}^{\hat{v}\left(k_{1}\right) \ldots \hat{v}\left(k_{n}\right)}\right. \tag{A4.4}
\end{equation*}
$$

so it will suffice to show that the righthand side of (A4.4) is finite. We break up the proof of this into three lemmas:
Lemma 18 Suppose $f$ and $\rho$ are in $L^{2}$. Then $\widehat{(f g)}=\hat{f} \neq \hat{g}$.
Even though this is well known we give a short proof here for completeness.
Prooft We have already seen in equation (A4.3) that the convolution $\hat{f} \pm \hat{g}$ converges absolutely. Recall that (Plancherel theorem)

$$
\begin{equation*}
\left\|g-\sum_{k=-M}^{M} \hat{g}(k) e^{j \omega k t}\right\|_{2} \rightarrow 0 \quad \text { as } \quad M \rightarrow \infty \tag{A4.5}
\end{equation*}
$$

-D. J. Newman, personal communicatioa.

By the Cauchy-Schwarz inequality

$$
\begin{equation*}
\left|\frac{\omega^{2 \pi}}{2 \pi} \int_{0}^{2 \pi-1} f(t)\left(g(t)-\sum_{k=-\infty}^{M} \hat{g}(k) e^{j \omega t t}\right) e^{-j \omega m t} d t\right| \leq\|f\|_{2}\left\|g-\sum_{t=-M}^{M} \hat{g}(k) e^{j \omega t t}\right\|_{2} \tag{A4.6}
\end{equation*}
$$

By (A4.5) the righthand side of (A4.6), and therefore the lefthand side of (A4.6), converges to 0 as $M \rightarrow \infty$. But the lefthand side of (A4.6) is just

$$
\mid \widehat{(f o})(m)-\sum_{k=N}^{N} \hat{g}(k) \hat{f}(m-k) \mid
$$

Letting $M \rightarrow \infty$ yields the conclusion.
Lemma $2 z v(t)^{n} \in L^{1}$ for all $n$. (That is, $v \in L^{p}$ for all $p<\infty$ ).
Prooft Clearly we need only worry about the singularity at $t=0$, that is $v(t)^{n} \in L^{1}$ if and only if $(\log (1-\cos t))^{n}$ is integrable near $t=0$. This is true iff $(\log t)^{n}$ is integrable near $t=0$, which is true since

$$
\int_{0}^{1}|\log t|^{n} d t=\int_{0}^{-\log t} e^{-5} x^{n} d x \leq n!
$$

which establishes lemma 2.0
Lemma 3:

$$
\begin{equation*}
\left\{\sum_{k_{1}+\ldots+k_{1}-m}\right\} \hat{v}\left(k_{1}\right) \ldots \hat{v}\left(k_{n}\right)=\left(v^{2}\right)(m) \tag{A4.7}
\end{equation*}
$$

Proots By induction on $n$. Suppose we have established (A4.7) for $n$. By lemma $2 v^{n}$ and $v$ are in $L^{2}$, so applying lemma 1 we have $\left(v^{n+1}\right)=\left(v^{n}\right)+\hat{v}$; using the inductive hypothesis

$$
\widehat{\left(v^{n+1}\right)}(\bar{m})=\sum_{n=\{ }\left\{\sum_{k_{1}+\ldots+t_{1}=m}\right\} \hat{v}\left(k_{1}\right) \ldots \hat{v}\left(k_{n}\right) \hat{v}(\bar{m}-m)=\left\{\sum_{t_{1}+\ldots+k_{2}=\bar{m}}\right\} \hat{v}\left(k_{1}\right) \ldots \hat{v}\left(k_{z_{i}+1}\right)
$$

the change of order valid since the summand is positive (Fubini Theorem). This completes the proof of lemma 3.0

We can now finish the proof of theorem A4.1.1. From (A4.4), (A4.7), and lemma 2 we have

$$
\left\{\sum_{k_{1}+\ldots+k_{1}-m}\left\|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n} \| \leq \beta^{n} \widehat{v^{n}}\right)(m) \leq\right\| v^{n} \|_{1}<\infty\right.
$$

establishing theorem A4.1.1.O
One useful condition which implies $\hat{u}(n)=O(1 / n)$ is that $u$ have bounded variation over one period.

Lemma 4.5.1: Suppose $\mathfrak{u}$ has bounded variation over one period. Then

$$
\left\{\sum_{k_{2}+\ldots+k_{2}=m}\left\|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{2}\right)\right\|<\infty\right.
$$

Prooft if $u$ has bounded variation over one period then $\hat{u}(n)=O(1 / n)^{24}$ (the proof is essentially integrating by parts the formula for $\hat{u}(n)$ ) and thus theorem A4.1.1 proves lemma 4.5.1. O

## As.2 Conditions on the Kernel $H_{n}$

Lemms 4.5.2z Suppose that $H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)=O\left(\frac{1}{k_{1} \ldots k_{n}}\right)$. Then (A4.1) is finite, that is:

$$
\left\{\sum_{k_{1}+\ldots+k_{1}=m}\left\|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right) H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)\right\|<\infty\right.
$$

Prooft Suppose $H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)=O\left(1 / k_{1} \ldots k_{n}\right)$. Then $H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right) \in I^{2}\left(Z^{n}\right)$. Since $\hat{u} \in I^{2}$, $\hat{u}\left(k_{2}\right) \ldots \hat{u}\left(k_{n}\right) \in I^{2}\left(Z^{n}\right)$ with norm $\|\hat{u}\|_{2}^{n}$ so the Cauchy-Schwarz inequality yields

$$
\begin{gathered}
\left\{\sum_{k_{1}+\ldots+k_{n}=n}\left\|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right) H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)\right\| \leq \sum_{k_{1}, \ldots, k_{1}}\left\|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right) H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)\right\|\right. \\
\leq\left\|\hat{u}\left(k_{1}\right) \ldots \hat{u}\left(k_{n}\right)\right\| k_{2}\left\|H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right)\right\|_{2}=\|\hat{u}\|\left\|_{2}^{n}\right\| H_{n}\left(j \omega k_{1}, \ldots, j \omega k_{n}\right) \|_{2}
\end{gathered}
$$

which proves lemma 4.5.2.

## A5. Almost Periodic Inputs

Recall that $\tau$ is said to be an $\epsilon$-translation number for $u$ if $\|u(\cdot)-u(\cdot+\tau)\| \leq \varepsilon . v$ is almost periodic if for all $\epsilon>0$ there is an $L$ such that all $L$-long intervals contain at least one $\epsilon_{0}$ translation number for u. Formally

$$
\forall \epsilon>0 \exists L \forall a \exists(a<r<a+L \text { and }\|u(\cdot)-u(\cdot+\tau)\| \leq \epsilon)
$$

These definitions and a concise discussion can be found in Wiener's book. ${ }^{27}$
Theorem A5.1z Suppose $u$ is almost periodic and $\|u\|<\rho=\operatorname{Rad} N$. Then $N u$ is almost periodic.
Proof Let $\epsilon>0$. Choose $r$ with $\|u\|<r<\rho$. By the Incremental Gain theorem (theorem 2.3.2) there is a $K$ such that on $B_{r}\|N u-N v\| \leq K\|u-v\|$. For any $r,\|u(\cdot+\tau)\| \leq r$, hence if $\tau$ is an $\in-$ translation number for $u$ then

$$
\|N u(\cdot)-N u(\cdot+\tau)\| \leq K\|u(\cdot)-u(\cdot+\tau)\| \leq K \epsilon
$$

so $\tau$ is a $K \in$-translation number for Nu .

Now to finish the proof: Since $\boldsymbol{u}$ is almost periodic find $L$ such that all $\mathcal{L}$-long intervals contain at least one $\epsilon / K$-translation number for $u$. From the discussion above these translation numbers are $\epsilon$-translation numbers for $N u$, thus $N u$ is almost periodic. O

We will now establish the analogous fundamental formula for almost periodic inputs.

## Theorem A5.2 (Fundamental Frequency Domain Formula for Almost Periodie Inputa):

 Suppose that $u$ is almost periodic and $\|u\|<\rho=\operatorname{Rad} N$, and in additionThen for any $\omega \in R$

Proof: Due to the similarity to the case of periodic inputs, we give a shortened proof. As in $\$ 4.3$ we first assume that the input has the form

$$
u(t)=\sum_{k=-M}^{M} \alpha_{k} e^{j \omega_{k} t}
$$

We will call such a e a multitone signal. It is easily verifled that for multitone signals

$$
\lim _{T \rightarrow \infty} \frac{1}{T} \int_{0}^{T} u(t) e^{-j v t} d t=\left\{\begin{array}{lc}
\alpha_{k} & \nu=\omega_{k}  \tag{A5.3}\\
0 & \text { otherwise }
\end{array}\right.
$$

The limit in (A5.3), which can be shown to exist for any almost periodic function and any $\nu \in R$, is denoted $\hat{u}(\nu)$. The same argument as in $\S 4.3$ establishes

$$
\begin{equation*}
\hat{N u}(\omega)=\sum_{n=1}^{\infty}\left\{\sum_{\omega_{k_{2}}+\ldots+\omega_{k_{4}}}\right\}^{\hat{u}\left(\omega_{k_{1}}\right) \ldots \hat{u}\left(\omega_{k_{0}}\right) H_{\mathrm{s}}\left(j \omega_{k_{1}}, \ldots, j \omega_{k_{0}}\right)} \tag{A5.4}
\end{equation*}
$$

for the case of $u$ a multitone signal. We now appeal to Bohr's characterization of almost periodic functions: they are precisely the uniform limits of multitone signals. ${ }^{27}$ Thus there is a sequence of multitone signals $u_{M}$ with $\left\|u_{M}\right\|<\rho$ and $u_{M} \rightarrow u$ uniformly as $M \rightarrow \infty$. By the Incremental Gain theorem $N u_{M} \rightarrow N u$ uniformly as $M \rightarrow \infty$. Hence for any $\nu$ in $R\left(\widehat{N u_{M}}\right)(\nu) \rightarrow \widehat{(N u)}(\nu)$. Since formula (A5.4) above holds for multitone signals we have

$$
\begin{equation*}
(\widehat{N u})(\omega)=\sum_{n=\{1}^{\infty} \lim _{N \rightarrow \infty}\left\{\sum_{\omega_{k_{2}}+\ldots+\omega_{k_{k}}=\omega}\right\}^{\hat{u}_{N}\left(\omega_{k_{1}}\right) \ldots \hat{u}_{M}\left(\omega_{k_{k}}\right) H_{n}\left(j \omega_{k_{1}} \ldots, j \omega_{k_{k}}\right)} \tag{A5.5}
\end{equation*}
$$

Since $u_{M} \rightarrow u$ uniformly, $u_{\mathcal{M}}(\omega) \rightarrow \hat{u}(\omega)$ uniformly. Dominated convergence and hypothesis (A5.1) yield

$$
\begin{equation*}
=\sum_{n=1}^{\infty}\left\{\sum_{\left\{\omega_{k_{2}}+\ldots+\omega_{k_{4}}-\infty\right.}\right\}^{\hat{u}\left(\omega_{k_{2}}\right) \ldots \hat{u}\left(\omega_{k_{n}}\right) H_{n}\left(j \omega_{k_{1}} \ldots, j \omega_{k_{n}}\right)} \tag{A5.6}
\end{equation*}
$$

which is the conclusion of theorem A5.2.O
